It is difficult, in a short review, to give an adequate idea of the contents of this volume, or essay, for it is essentially an extended discussion. The reader, however, may be assured that it not only touches on many of the main features of morphogenesis, as presently understood, but also that it is the product of much thought and bears the impress of a philosophic mind. C. W. WARDLAW

GENERAL DISCUSSIONS ON CHEMISTRY

Heterogeneous Catalysis

(Discussions of the Faraday Society, No. 8.) Pp. 366. (Aberdeen : Aberdeen University Press, Ltd., 1950.) 30*s*. net.

Colloques Internationaux du Centre National de la Recherche Scientifique

10 : Réactions dans l'état solide, Paris, Octobre 1948. Pp. iv+222. 1100 francs ; 25*s*. 30 : Réarrangements moléculaires et inversion de Walden, Montpellier, 24–29 avril 1950. Pp. 152. 2000 francs ; 44*s*. (Paris : Centre National de la Recherche Scientifique ; London : H. K. Lewis and Co., Ltd., 1949–51.)

Institut International de Chimie Solvay

Huitième Conseil de Chimie tenu à l'Université de Bruxelles du 10 au 15 Septembre 1950. Le mécanisme de l'oxydation ; Rapports et discussions. Pp. iii+503. (Bruxelles : R. Stoops, 1950.) 550 francs.

ALTHOUGH general discussions and symposia on selected topics are recognized features of scientific life, it is somewhat doubtful whether the publication of the proceedings contributes very much to the edification of the general reader. The papers presented are not often novel and generally consist of material already published, presented in such an abbreviated form that they are unintelligible except to specialists, and the discussion is usually chaotic and composed of fragments which are mutually self-destructive. The Faraday Society seems to have felt this situation, since its discussions are prefaced by summaries or surveys which try to make some sort of coherent picture of what occurred. It is no doubt true that the proceedings are stimulating to the participants ; but the average scientific reader, in search of concrete information, may sometimes feel that, having fulfilled this purpose, they might well have ended there. A report prepared by an independent author is usually much more intelligible and informative.

The Faraday Society discussion on heterogeneous catalysis comes off rather well in these respects, since it includes some important new material in the experimental field, and although the subsequent discussions of the papers are on the familiar lines, they do not occupy too much valuable space. The introductory paper, by Prof. H. S. Taylor, is readable and informative. Some of the outstanding difficulties and contradictions in the field are dealt with in other papers. The section on techniques brings together some valuable information on modern methods. The whole volume is well above the usual standard of such discussions and cannot fail to be useful both to specialists and those whose interests are more general.

The two "Colloques Internationaux" are less praiseworthy. The articles are too numerous and too brief to be wholly intelligible, and the volumes leave a feeling of surfeit and mental dyspepsia which they are bound to produce in such a form. The topics are of great interest and importance ; but the treatment as a whole does not present a coherent picture of the state of the subjects. All the same, the volumes will be found useful in a limited field. Readers who know little of the subjects will not know very much more after reading the fragments. It is suggested that a smaller number of contributions, more adequately treated and with some regard to the needs of non-specialists, would be more suitable. No doubt the participants gained much from the proceedings ; but they might well have been satisfied with this and let the matter rest. May we hope that future publications will be more attractive to the general scientific reader ?

The report of the eighth Solvay Congress contains some papers of reasonable length, carefully prepared and clearly presented. They are all intelligible and valuable, and a reader will gain real information from them. The field covered is wide, and includes the important biological aspects. The authors do not assume that the reader already knows what is in the papers, and in general lay the foundations well. The mathematical treatment is limited to what is really essential, and is adequately related to the experimental material. The discussions are often confused and unnecessary. The bibliographies are extensive and good. The subject of the mechanism of oxidation, in its present stage of development, is difficult and most important, and this volume may be said to clarify and unify a good deal of scattered material in a very satisfactory way. Some important newer reagents such as periodic acid have found extensive applications but are still not adequately treated in the detailed text-books. They are well represented here. The whole volume is sure of a welcome from many kinds of readers. J. R. PARTINGTON

BRITISH AMATEUR ORNITHOLOGIST'S VADE-MECUM

The Pocket Guide to British Birds

By R. S. R. Fitter. Pp. xvi+240+112 plates. (London and Glasgow : Wm. Collins, Sons and Co., Ltd., 1952.) 21*s*. net.

THIS text-book aims at presenting British birds accurately to the beginner by coupling Mr. R. A. Richardson's fine illustrations with the use, not of measurements and technical descriptions, but of a simple classification into eight groups : very short, short, medium short, medium, medium long, long, very long, and huge. There are also wing, neck, leg and bill ratios in similar categories. It seems a pity that the length of each bird is not given in inches, so that if the student finds himself very close to, or able to handle, a wild bird, he can check by measurement. To some extent the artist has overcome this difficulty by providing a silhouette of a sparrow upon each page of illustrations.

The beginner who may be at first confused by the novel classification in this book should take heart from Mr. Fitter's observation that even the expert cannot be confident about the identity of some of the "small brown birds", unless they call or sing, when the novice possessed of a good ear may as quickly recognize the species; and he may turn to the key at the end of the book for alternative methods of identification—colour, structural features, behaviour, voice and habitat. There are a calendar of migration and breeding periods, lists of geographical races and rare visitors, and an index. About half a page is devoted to each common (or not very rare) British bird, and this section forms the bulk of the highly condensed but accurate text. The first to be described is the smallest, the goldcrest, classified under "Land Birds: Very Short". The last is the mute swan—under "Water Birds: Huge". Sensibly included are some introduced semi-feral species. Chinese goose, mandarin duck, 'London' pigeon and budgerigar, for example, are described; and they are likely to confuse the amateur in search of indigenous species, unless he is warned about these 'foreigners'.

This guide depends upon the success of Mr. Richardson's six hundred colour and four hundred black-and-white illustrations, of which Mr. Peter Scott, himself responsible for some free-flying non-indigenous wildfowl in Britain, says in the foreword that "nothing of the kind has been so well done in Britain before" and "a new bird painter of great skill has entered the field". I am inclined to agree that the combined efforts of artist and colour processor have been successful in overcoming the difficulties of presenting the fine differences of shade and tint between related species, to a degree not so uniformly attained before. The warblers have not been, and may never be, portrayed in colour to the satisfaction of the expert, so delicate and changeable are their tints, according to the strength of the natural light. It was a good plan to show alike-coloured, even though otherwise unrelated, species on the same page. The black-and-white illustrations are mainly of birds in flight, usefully showing wing-pattern and form. The whole seems to justify the claim on the jacket, of a pocket-guide which is also "the complete identification book".

R. M. LOCKLEY

HISTORY OF THE NORTH AMERICAN BUFFALO

The North American Buffalo

A Critical Study of the Species in its Wild State
By Frank Gilbert Roe. Pp. viii+957. (Toronto: University of Toronto Press; London: Oxford University Press, 1951.) 90s. net.

IT is unfortunate that our thirst for knowledge of the larger forms of wild-life often postdates their partial or complete elimination. Inevitably, perhaps, the pioneers of a spreading civilization have little interest in preserving, much less documenting, the natural features of the new worlds they open up. As a consequence, we are compelled to search diligently among the ruins for scraps of knowledge in order to build up even an inadequate story of what has been lost for ever. The story of the North American buffalo is but one of many, and in this book the author, after years of research, has written a thousand pages closely documenting the history of the buffalo, from its first discovery in 1530 to its virtual extermination in the 1880's.

Dr. F. G. Roe's text reads like a legal judgment, an objective recital of all the available evidence, with little sign of the possible verdict until, towards the end and preceding the four hundred pages of appendixes, bibliography and general index, he gives a few pages of concluding summary. The twenty-four chapters deal with the general characteristics of the buffalo, and with its habitat, but more especially with its former numbers, the regularity or otherwise of its behaviour, and its influence upon the Red Indians who occupied the same territory. Throughout, his approach is avowedly iconoclastic, and it is perhaps in a subconscious attempt to counteract this that his effort to maintain an objectivity leads to a certain obscurity in the writing.

It is the common practice in referring to the North American buffalo always to speak of their countless millions that blackened the plains. Dr. Roe seems to think that, even as a mere figure of speech, this is widely misleading, and he takes his reader through an analysis of a large quantity of reports and statistics to prove it. Yet there is more support for this contention in the evidence he brings forward to prove his second point, that the erratic habits of the buffalo accounted for the peculiar nomadism of the Indians of the plains.

Our modern information tends to suggest an almost clock-like regularity in the habits of wild animals, so that the idea of anything—bird, beast or even porpoise—wandering or behaving fancy-free is regarded as somewhat old-fashioned. In strong contrast to this, a case is made out in this book for believing that the behaviour of buffalo, singly or in herds, was strongly individualistic. The author goes so far as to reject any notion of vast seasonal migrations. His views are unorthodox, also, in regard to the habits of wolves. Observations in recent years on the North American wolf have suggested a remarkable regularity in its habits, but the evidence put forward by Dr. Roe leads him to suppose that the wolves formerly preying on the buffalo were compelled to an erratic nomadism in order to follow their supply of food. Moreover, he believes the Indians of the plains owed their nomadic habits to that same need for keeping in touch with their main source of subsistence, and he postulates a definite link between the presence of this inexhaustible supply of food and the Indian mentality and general outlook on life. Incidentally, he exonerates the Indians from the criticisms of wastefulness in their slaughter of the buffalo and fixes the blame very certainly on the improvident white settler.

Another conclusion given by Dr. Roe in his summary, especially interesting since he is an engineer by profession and not a biologist, is the more remarkable in that it is reached by way of a severely objective study of documentary evidence. To the many zoologists to-day who deny intelligence in any but the human species, with perhaps a dawning intelligence in the higher apes, Dr. Roe points out that, if the theory of evolution means anything, it must mean that "the dawning of the capacity for individual impulse *must begin somewhere*" (his italics), and he conceives "of no sound reasons why this should not apply to the buffalo species". Finally, "In relation to buffalo in particular, the most philosophic and generally reliable historian of the species at . . . large explicitly credits them with a degree of individual variation in conduct which can scarcely be ascribed to anything else than some form of personal intelligence, define it how we may".

MAURICE BURTON

THE ROYAL SOCIETY

ANNIVERSARY ADDRESS BY DR. E. D. ADRIAN, O.M., F.R.S.

AWARD OF MEDALS, 1952

Copley Medal

THE COPLEY MEDAL is awarded to Prof. Paul Adrien Maurice Dirac for his remarkable contributions to the quantum theory of elementary particles and electromagnetic fields. All his work has a very distinctive quality, in that he has known how to make evident the relationship of the remote abstractions of the pure mathematician to the extremely practical problems facing the atomic physicist. This appeared even in his earliest work, for in 1926 he took up the non-commutative algebra of Heisenberg, and solved the problem of a non-commutative planetary orbit. Not long afterwards, he showed how the 'matrix mechanics' of Heisenberg could be identified with the 'wave mechanics' of Schrödinger. It is this paper, with its development of the idea of 'representations of physical states', that more than any other has given the colour of his work.

The advances made in 1927 had not provided a relativistically invariant mechanics for the electron, nor had they explained the phenomenon of 'electron spin'. In 1928 he remedied both of these defects at the same time. Perhaps the deepest quality of this work was that it replaced the second-order equations, previously universal in wave-theory, by equations of the first order. These equations had some astonishing consequences, such as possible states of negative kinetic energy; and Dirac attempted a physical interpretation of these states by the concept of a background of electrons occupying nearly all such states. An unoccupied state appeared in the physical world to be a particle of electronic mass and positive charge, equal in magnitude to that of the electron. The 'positive electron' or 'positron' was actually only discovered several years later, and it fitted into Dirac's scheme.

During the same period he was responsible for another discovery of the very first importance, the Fermi–Dirac statistic which was independently formulated by both these authors. Dirac began with the conception that electrons are all identical, and made the point that unless electrons obeyed this statistic it would be possible to recognize their individuality; this is a typical example of the manner in which he has known how to devise the most practical conclusions from the most abstract principles. It was this statistic which served to explain the nature of the conduction of electricity in metals, one of the most formidable difficulties of the older physics.

Some of Dirac's most brilliant work was done at Cambridge while he was a Senior Student of the 1851 Exhibition. He was elected a Fellow of the Royal Society in 1930, the year in which appeared the first edition of his book, "Principles of Quantum Mechanics". This book has the highly individual character of all its author's work; considering the novelty and difficulty of the subject, its clarity of style and directness of approach are models of what a scientific text-book should be. Dirac was appointed to the Lucasian chair at Cambridge at the early age of thirty and was awarded a Nobel Prize in Physics, jointly with Schrodinger, in 1933.

Rumford Medal

The RUMFORD MEDAL is awarded to Prof. Fritz Zernike. In the year 1934 Prof. Zernike described a simple method of indicating the absolute errors in the surfaces of concave spherical mirrors. Realizing that minute defects in the regularity of the surface would give rise to diffraction images out of phase with the central image, he proposed the use of a phase plate to neutralize this difference. Interference then takes place, and on looking through the phase plate the position and magnitude of any irregularities are clearly indicated and may be retouched as necessary. A year later Zernike applied a similar method to the microscope, with results of far-reaching importance.

During the long period of the evolution of the microscope, there have been periods of quiescence and of great activity—the latter always stimulated by some outstanding individual. Of these periods it is only necessary to refer to the close of the past century when Abbe made what then appeared to be an exhaustive study of the light distribution in the back focal plane of the objective. He showed that objects with a highly organized structure gave rise to a series of diffraction spectra of the zero, first and higher orders.

It was then assumed that a transparent phase object must of necessity give rise to an image of low contrast unless suitable staining techniques could be employed to differentiate clearly between the various structures forming the object. The phase object was thereby converted into an amplitude object by means of elaborate techniques which gave rise to changes in the object and in some cases to artefacts. These methods could not, of course, be applied to living material.

By slightly modifying a standard microscope, Zernike showed that it was possible to neutralize the phase difference existing between the spectra of zero and first orders, and thus by interference to transmute the invisible changes of phase produced by the object into changes of amplitude in the resulting image. Living transparent cellular structures are by this means imaged in contrast in such a manner that for small phase changes the depth of tone at any image point is proportional to the phase change brought about at the corresponding object point.

To summarize, Zernike was the discoverer of a new and most valuable microscope technique, an advance comparable with that contributed by Ernst Abbe towards the close of last century. Phase-contrast microscopes are now in daily use in laboratories throughout the world. Science is also indebted to Zernike for many valuable contributions to the underlying mathematical theory. Zernike's work has also acted as a great stimulus to the study of diffraction phenomena and has led indirectly to other important advances in the field of interferometry.

Royal Medals

A ROYAL MEDAL is awarded to Prof. Christopher Kelk Ingold, professor of chemistry in the University of London and director of the Chemical Laboratories at University College, for his extensive investigations of the mechanism of, and the factors influencing, organic reactions.

Over many years it has been Ingold's purpose to treat the mechanism of organic reactions in a quantitative fashion and to understand the factors influencing such reactions in terms of fundamental physical chemical concepts. Thus, for example, in the very early days he made the first successful attempt to understand the interaction between two ions, and between an ion and a permanent dipole, in terms of quantitative electrostatic factors, and applied this work to the velocity of esterification and hydrolysis.

Ingold and his co-workers, for the first time, gave a complete elucidation of the reaction between an ion and a polar molecule. They have studied the influence of substituents on the velocity of organic reactions and have made the most detailed and beautiful analysis of the structure of benzene. All this work is characterized by detailed experimental investigation in which quantitative data on the mechanism of reaction have been obtained. On this quantitative work it was possible for Ingold to base a detailed theoretical framework, and it would be fair to say that no man has contributed with such detailed exactness and with such breadth of theoretical vision to our knowledge of the mechanism of organic reactions as has Ingold. Moreover, his work and ideas are not only applicable to the particular reactions which he has studied. His ideas are at the very basis of quantum chemical theory: in some cases he has anticipated quantum mechanical ideas —in others he has been quick to see the application of such ideas to his own work.

A ROYAL MEDAL is awarded to Sir Frederic Bartlett for his work on experimental psychology. The School which he founded at Cambridge on the beginnings made by Rivers and Myers became, under his leadership, the dominant school in Britain and one of the most famous and respected in the world. There were good reasons for this. Bartlett, at the beginning of his career, saw in mental process a field for experimental observation complete in itself, independent both of philosophical theories and physiologists' stimulus-response investigations. He very early recognized the many factors that enter into these responses and saw that they could be explored in manual and bodily action, in hand skills and skills at games, as well as in verbalizations. An interesting point was his discovery of the important part played by memory of previous performance in maintaining or increasing an individual's skill. His work has always shown great originality of method, unusual power of penetrating a problem and fertility in discovering analogous subjects for experiment. While realizing their validity in certain respects, he has shown a refreshingly critical judgment of the limitations of statistical methods in biology, and he has done much to prevent modern experimental psychology from degenerating into the composition of graphs and arithmetical tables.

His book on "Remembering" (1932) is a classic of psychological research, emphasizing the effects of social conventions and different ways of living on performance and response. During the Second World War, Bartlett and his pupils in the Cambridge laboratories did a great deal of research for the Services, especially on the effects of fatigue in diminishing quality of performance in pilots and the complex factors that facilitated it. Since then his advice has been eagerly sought in industrial personnel problems.

Bartlett's output has been considerable, but it is the clarity and conciseness of his thought which has made his experimental results so fruitful.

Davy Medal

The DAVY MEDAL is awarded to Prof. Alexander Robertson, professor of organic chemistry in the University of Liverpool. He achieved a world-wide reputation as an authority on the organic chemistry of those natural products belonging to the class of compounds containing heterocyclic oxygen atoms. Arising from his early studies with Sir Robert Robinson on anthocyanidins and anthocyanins, Robertson developed an interest in the natural glycosides, and his first major studies were in this field. He developed new methods of synthesis for biosides of phenols, and by a combination of analytical and synthetic procedures he established the structures of a large number of these substances, including indican, the natural glycoside of the indigo plant, and ruberythric acid, the glycoside of madder.

Following on these investigations, he commenced his long series of studies of hydroxy-carbonyl compounds, and on heterocyclic oxygen compounds of natural occurrence. Compounds of these types include many of the familiar non-nitrogenous bitter principles of plants, as well as a variety of fish poisons and insecticides. Over the past twenty years Robertson's output of research in this field has been prodigious, and his work throughout has been marked by brilliance, alike in perception and execution. Among his many triumphs may be mentioned his clarification of the chemistry of the rotenone group of insecticidal compounds from derris root, of usnic acid from lichens, and of the complex natural colouring matters, rottlerin from kamala, dracorubin from dragons blood resin, and the pigments of the insoluble red woods. It is worthy of particular mention that in all these cases Robertson was dealing with problems which had baffled many investigators and were regarded as chemical puzzles; such they would have remained but for his brilliant synthetic studies on oxygen-ring compounds in general. Further development from this point led to his clarification of the structure of the natural furano-coumarins and furano-chromones and of the mould colouring matters, citromycetin and citrinin. In another colouring matter isolated from a micro-organism, violacein, Robertson encountered the remarkable oxidation of hydroxy-indole derivatives, which is bound up with the problem of melanin formation in animals, and he has since then made, and continues to make, notable contributions to our knowledge of the mechanism of melanin formation.

In short, Robertson is a brilliant organic chemist, who has not only solved a long series of structural problems which had baffled earlier workers, but in so doing has opened up new fields of study.

Darwin Medal

The DARWIN MEDAL is awarded to Prof. John Burdon Sanderson Haldane, Weldon professor of biometry in University College, London, for his work on the analysis of the causes of variation and of the mechanism of selection. The conclusions derived from his researches have permeated practically every field of evolutionary discussion, and his ideas have fundamentally altered our knowledge of evolutionary change.

For many years he has insisted that a proper study of evolution involves the development of methods for investigation of the genetics of populations. His mathematical treatment of the question was the first of its kind, and has played a large part in the great development of understanding of evolution during the past twenty-five years.

He has been a pioneer in applying biochemical knowledge, especially of enzymes, to problems of genetics. His contributions to strictly genetical problems are fundamental. They included some of the earliest demonstrations of linkage in birds and mammals and of partial sex-linkage in man. He made the first investigations of human mutation-rates (simultaneously with L. S. Penrose), has studied interspecific hybrids and discovered the rule by which their sex is determined. He was one of the first to develop a theoretical treatment of polyploidy and to show its evolutionary significance.

He has thus made first-rate contributions by his detailed researches, his mathematical treatments and his general analysis of evolutionary problems, to the field of Darwin's work.

Buchanan Medal

The BUCHANAN MEDAL is awarded to Sir Rickard Christophers. Many of the early papers by Christophers appeared in the reports to the Malaria Commission of the Royal Society from 1900 onwards. He was one of the two principal authors of these reports, which make a fundamental contribution to our understanding and prevention of malaria, the greatest cause of sickness in the tropics.

Fifty years ago, Christophers originated the fundamental idea that malaria is not transmitted by *Anopheles* mosquitoes in general but by certain species of *Anopheles*, not by others: much turned on the insect's choice of host, and both in Asia and Africa it was shown that different species of *Anopheles* breed in different types of water: the control of the dangerous species is still based on this, and 'species sanitation' constitutes a fundamental advance in public health.

Turning to the disease itself, Christophers distinguished several main types in the epidemiology: he developed new quantitative methods. He observed that, in such a region as the Punjab, people are not soaked in malaria; they possess, therefore, little immunity, with the consequence that immense fulminant epidemics may occur at intervals of a few years. This he contrasted with the hyper-endemic type of malaria which occurs in places where people are exposed to malaria at all seasons and in every year; in such places the disease may indeed be grave, especially to children, but it does not occur in great outbreaks.

It is not too much to say that nearly all our basic knowledge of the conditions leading to the spread of malaria arises from investigations carried out, mostly in India, by Christophers and those immediately associated with him.

Sylvester Medal

The SYLVESTER MEDAL is awarded to Prof. Abram Samoilovitch Besicovitch, Rouse Ball professor of mathematics in the University of Cambridge. Besicovitch left Russia in 1925 and came to Great Britain after working for a short time with Harald Bohr in Copenhagen; he is one of the foremost authorities in the world on the theory of plane sets of points and the area of surfaces. His first notable work lay in the generalization of the theory of almost periodic functions of Harald Bohr. By dropping the condition of continuity of the functions, he obtained a theorem of the Riesz–Fischer type, thus rounding off the theory in an essential point. Later, and in collaboration with Bohr, he showed how to develop the whole theory from the point of view of function spaces. His book, published in 1932, is still the standard work on the analytical side of the theory.

During the 'thirties he published a large number of papers on various topics of analysis; but probably the most significant of his papers in this period are those devoted to the study of the structure of sets of points in the plane, which are among the deepest and most original contributions to modern analysis.

In recent years he has made a number of fundamental contributions to the theory of the area of surfaces in space. He has also solved a number of isoperimetric problems and made a very important contribution to the additive theory of numbers.

Hughes Medal

The HUGHES MEDAL is awarded to Prof. Philip Ivor Dee, who is distinguished for his application of the cloud-chamber technique to the study of nuclear transmutations. After early work with Prof. C. T. R. Wilson, he studied the interaction of neutrons with electrons immediately after the discovery of the neutron by Chadwick, and showed that the neutron–electron interaction was extremely small. He then applied the cloud chamber to the study of the transmutations of lithium and boron by high-speed protons which had been discovered by Cockcroft and Walton. His very elegant photographs showed directly and proved conclusively the disintegration of boron into three alpha-particles. He then turned to the study of the disintegrations produced by heavy hydrogen, which had been discovered by Rutherford and Oliphant. The cloud-chamber evidence proved that the disintegration of deuterium by deuterons could take place either into a proton and a triton or into a neutron and helium-3. This is one of the most important of the nuclear transmutations.

Dee was then largely responsible for the design and installation of the one-million volt proton/deuteron accelerator in the Cavendish Laboratory during 1936–39. This equipment was remarkably successful and has been copied by numerous laboratories. It enabled a new series of refined experiments on nuclear transmutations to be undertaken. Under his direction, the High Voltage Laboratory carried out a large number of investigations on the transmutation of the light elements which clarified many important aspects of such transmutations.

Dee left the Cavendish Laboratory with his group on the outbreak of war in 1939. He was responsible at the Telecommunications Research Establishment for the development of the technique of microwave radar—probably the most important technical development of the War.

At the end of the War he was appointed to the chair of natural philosophy in the University of Glasgow and has there built up an active school of nuclear physics. He has equipped a high-voltage laboratory, and installed a 30-million volt electron synchrotron and a 330-million volt electron synchrotron. He has recently published an important paper with Richards showing that alpha-particles produce chemical effects in liquids through the interaction of short-wave radiation.

The Council has already presented to the Fellows its report on the work of the Society during the past year—the 290th year of its existence. It was a year in which we had to sustain a grievous loss in the death of our Royal Patron, King George VI. The Queen has been graciously pleased to become Patron of the Society, and the Fellows will rejoice to know that our historic Charter Book is now adorned with Her Majesty's signature on the appropriate heraldic page, a reminder of the great privileges which the Society has always enjoyed since the days of its Royal Founder.

There are certain items in the Council's report to which I may refer. There is, for example, the encouraging fact that the delays in publication of papers in the *Proceedings* and *Transactions* show a steady reduction. The average time between the receipt of a paper and its publication has been 26 weeks for *Proceedings A*, and since June 12 papers have taken less than 20 weeks. But costs continue to rise and, apart from our own publications, there is the very serious problem of financing the publication of abstracts, particularly in the field of chemistry. We must not rely unduly on the help of industry and of Government funds for such important work; but I should like to take this opportunity of thanking those industrial concerns which have contributed so generously towards it. All of us, scientists, industrialists and Government alike, know the great value of our abstracting publications, and none of us can afford to relax our efforts to keep them flourishing.

These abstracting services show us how scientific knowledge is expanding; but before tendering advice about them we ought, no doubt, to set our own house in order. The Royal Society Library contains a wealth of scientific material and papers not yet adequately catalogued: we were most grateful to the Pilgrim Trust for the grant it gave three years ago to enable us to make a calendar of the Society's papers from 1800 onwards, and it has now earned our renewed gratitude by providing a further grant.

One other benefaction should be mentioned. As the Treasurer reported last year, the Society has received the sum of £70,000 on account of the John Joseph Jaffé bequest. During the year we have been able for the first time to award a "Mr. and Mrs. John Jaffé Donation" from this bequest. This first award was made to Sir Geoffrey Taylor, who retired from the Yarrow professorship in February 1952 but continues to direct an important research programme in Cambridge. When we receive the whole of the bequest, we look forward to making many further awards in a manner which will be in accordance with the wishes of the donor and will render great service to the advancement of science. We are very grateful to the late Mr. Jaffé for this bequest.

There is one item which concerns our staff. At the end of the year Mr. P. D. Rogers, deputy assistant secretary, is due to retire from the Society's service after being with us for more than forty years. He began as a junior when Sir Archibald Geikie held office and has served in all under ten presidents of the Society. He is now our Clerk of Council, and the Society will know that the smooth running of our business owes much to the care and efficiency of his work. During these past forty-one years he has seen the Society's responsibilities expanding over a wider and wider field. We are extremely sorry to see him go and we congratulate him on his long and successful career at Burlington House.

NEW TECHNIQUES IN THE STUDY OF THE NERVOUS SYSTEM

It is not usual at the anniversary meeting of the Society to give more than the names of those Fellows of the Society who have died during the year, but there is one of them who occupied a special place as much by reason of his personal qualities as of his great services to science over many years. Charles Scott Sherrington was president during 1920–25, he was a physiologist of world-wide renown, a man of letters as well as a scientist and one who inspired universal affection. Few scientists of our time have been so well qualified to judge the advance of human understanding of the natural world, for he lived long enough to have witnessed most of the great achievements of the present era and he had made an intimate study of the science of the Middle Ages, when the schoolmen and the alchemists were as satisfied with their theories as we are with ours.

But Sherrington was primarily a physiologist and so was interested in the development of ideas concerning the living organism—"Man on his Nature". In his own work he had seen the transformation of physiology from a science still largely anatomical and concerned with the description of bodily adjustments into one which is more concerned with the cell and makes full use of the most advanced techniques of physics and chemistry. His work reflected this change in that his earlier experiments dealt with reflex movements and his later with the control of the individual motor units; but its enduring quality comes from the fact that he was always alive to the whole range of biological inquiry. He thought of cell activities in their relation to the organized behaviour of the whole animal.

He studied the integrative action of the nervous system. That was the title of his classical series of lectures published in 1906. His method was to select a relatively simple movement which could be evoked under standardized conditions, like the withdrawal of the foot from a noxious stimulus, to study the whole apparatus of sense organs, nerve fibres and central cell stations concerned in such a reflex and by doing so to establish the general principles by which simple movements are compounded to give more elaborate activity.

His book was reprinted by the Physiological Society when the International Congress met in Oxford in 1947. It needed no alteration, and although a great deal had been found out about the nervous system since 1906, the general conclusions are still the only general conclusions which can be drawn. But this is not so much a confession of the failure of neurologists to solve their problems as an index of the fundamental difficulty, at all events the fundamental nature, of the main problem, which is to construct a physiological picture of intelligent behaviour.

So much has been written about this in recent times that there is no point in elaborating it now, but our picture of the nervous system is extending in several directions; changes of emphasis have followed new techniques and it may be worth considering where they may be expected to lead.

The most striking advance has come from the great development of techniques for studying what goes on in the very small units of which the nervous system is built up. The new methods of microscopy are scarcely old enough to have borne fruit, but the electronic amplifier has made it a relatively simple matter to study the electrical activity of single nerve cells, and there are corresponding advances in the technique of manipulating very small and delicate living structures.

An early result of the introduction of the amplifier was to establish the nature of the signals by which the nervous system carries out its business. They are all of them trains of nerve impulses, brief outbursts of activity revealed by their electrical effects, travelling rapidly along the nerve fibres and succeeding one another at intervals as short as 1/1,000 sec. Recording them has shown what kind of information can be carried by the nerve fibres and how the sense organs react to stimuli.

But although these electrophysiological methods have been in use for upwards of twenty-five years, our knowledge of the sense organs is still very far from complete. It has been biased, naturally enough, in favour of human sense organs, and it is only in recent years that we have begun to learn much about the sense organs of animals constructed on a different plan or for a different environment. For example, the most remarkable because the most unexpected recent addition to sensory physiology has been Lissman's discovery that certain fish can guide themselves by the aid of the currents which they produce from special electric organs in their bodies. The massive electric discharge of the torpedo was described in a communication to the Royal Society by Walsh in 1773. It is powerful enough for the torpedo to use it as a weapon of offence; but it appears that various freshwater fish have electric organs too small to have any paralysing effect, but large enough to set up pulses of current in the water for their own sense organs to detect. Regions of different conductivity near the fish will distort the pattern of current flow, and if the sense organs are adequately spaced they will reveal the distortion and therefore the presence and the position of the object. Those who attended the soirée last May will have listened to these guiding discharges made audible by connecting electrodes in the water to a loud-speaker system. Bats are known to guide themselves by the sounds they produce, and this is another example of an animal generating the stimulus to be used by its own sense organs. Mankind has learnt to produce such guiding stimuli artificially, as when we light a lamp to see our way in the dark, but the sense organs were evolved without consideration of all that man might do. Our semicircular canals are excellent devices for signalling the limited rotation of the head on the trunk; but they are worse than useless if we subject ourselves to continued rotation on a turntable. In the same way this electric signalling system in fish breaks down when faced with the results of human activity. Rushton has recently investigated the reactions of the eel, *Gymnotus*, an animal which has two kinds of electric organ, a larger one for stunning its prey and a smaller one for detecting it. The system enables the eel to detect and eat the small fish, which in natural surroundings are the only objects likely to have a high conductivity, but if metal electrodes are placed near it the eel detects and eats these too. Indeed, the stomachs in electric eels which have lived in civilized regions are said to contain an assortment of scrap metal erroneously swallowed because the electrical detecting system was not designed to exclude such man-made objects.

Animals which live on land could have little use for organs the sole function of which is to produce electric currents, but small electric currents are, in fact, produced whenever nerve fibres or nerve cells are in action. These action currents are due to ionic interchanges at the cell surface. They play an essential part in nervous transmission; but their study is important not only because they show how information is transmitted but because they give a clue to the molecular changes in the cells. The biophysical problems arising from the phenomena of animal electricity have been recognized since the days of Galvani, and it is in this field that the most rapid progress is now taking place.

It has come from three technical developments: the use of very large nerve fibres, of very small exploring electrodes and of radioactive tracers. All three contribute to the study of the living cell surface and the molecular changes which it controls. Most vertebrate nerve fibres have a diameter of less than 10 μ, and a single fibre is formidable material for the biophysicist; but the giant nerve fibres of squids are large structures, half a millimetre or more in diameter. They were introduced to physiology by Prof. J. Z. Young, and their use has made it possible to study the interior of the fibre as well as the exterior. Later it was found by Ling and Gerard that tubular electrodes of hard glass, with a diameter of 1 μ or less, would penetrate the cell membrane without appreciable damage, so that results obtained with giant fibres can now be extended to other types of cell structure.

The results have given us a new outlook on cell activity. This year, for example, Prof. A. L. Hodgkin and A. F. Huxley read a paper to the Society describing the sudden changes in permeability which occur in the cell membrane when it is subjected to a current which tends to depolarize it. It used to be thought that the result of depolarization was to make the membrane generally permeable to all ions, but the change is much more remarkable; in fact, during activity the relative permeability to different ions is the reverse of what it is during rest.

At rest there is a higher concentration of potassium and a lower concentration of sodium ions in the fibre than in the fluid outside it, and the surface membrane prevents the free diffusion which would equalize these differences. During each pulse of activity, started by depolarizing forces, there is a sudden movement of sodium into the fibre, succeeded almost at once by a movement of potassium out of it. The actual entry of sodium and loss of potassium ions has been measured quantitatively by Keynes and others using radioactive ions. The quantities involved in a single impulse are very small; Keynes and Lewis reckon it as 3–4 μμ mol. through 1 cm.^{2} of surface, but to maintain its state the fibre must restore the potassium it loses and get rid of the sodium which it gains at each impulse.

The biophysicist has therefore two sets of problems to study: those of the surface membrane, which starts and stops this ionic interchange; and those of the cell metabolism, which keeps up the differences in concentration of sodium and potassium in the resting state, pumping out the sodium and restoring the potassium. As Hodgkin points out, although the loss for each impulse in the giant nerve fibre of the squid is only a millionth of the total internal potassium, in the very fine dendrites of the central nervous system the internal store would fall much more rapidly if it were not replenished. Where continuous activity is the rule, as in the controlling regions of the central nervous system, there may well be considerable fluctuations in the internal levels of potassium and sodium ions which may have a profound effect on the working of the cells and about which we are still completely ignorant.

This attack at the biophysical level is beginning to reduce the problems of cell organization in the nervous system to the molecular level. It is likely to explain many of the characteristic properties of nervous tissue, and certainly a clear picture of the cell mechanism must be the basis for any picture of the nervous system as a whole. But the title of Sherrington's book reminds us that most of the picture is very far from clear. The cell units are there to give the integrative action of the whole animal, and we have to find out how they are organized into the nervous system as well as how each one stores and discharges ions.

The problem of organization is partly anatomical—deciding what each fibre tract and cell mass contributes to the total activity. Here there has been and will be a steady advance. But the special feature of the nervous system is the wide variety of action it controls and its power to make behaviour appropriate to future as well as to present needs. It is, in fact, the great diversity of its interests which makes it so difficult to proceed.

Since we are still searching for the physical changes which accompany learning, the changes—structural or molecular—which make the nervous system react differently after training, there is little as yet to bridge the gap between the biophysics of the nerve cell and the fully elaborated activity of the whole system. If we could find, for example, the cell changes which establish a conditioned reflex, we should still have only the general principles of nervous organization. We could not forecast in detail how any particular nervous system would react unless we knew every detail of its past history.

The sort of difficulty which confronts us in studying the organization of the brain is illustrated by recent work which aims at plotting by electrical methods the more remote consequences of the arrival of a sensory message in the brain. Lilly in the United States and Grey Walter in Britain have already made some very interesting observations by different techniques; but to describe their results adequately is already a considerable feat, involving the reduction of four-dimensional patterns to a two-dimensional page.

To understand the integrative action of the nervous system we have to relate the unit to the whole system and the system to the work it has to do. The study of the unit is advancing rapidly, though it is mostly concerned with the immediate response to stimulation and we know little about slower and more persistent effects. When we do know more, it may be that the general plan on which the units are organized will become much clearer. Perhaps a complete revision of outlook may be necessary. At all events there is no need to be pessimistic. There is a wealth of new material and new methods, and a branch of natural science is in a healthy state when it has advanced to the stage where its traditional conceptions begin to look inadequate.

BIOLOGY OF DESERTS

A SYMPOSIUM on "The Biology and Productivity of Hot and Cold Deserts", organized by the Institute of Biology, was held at the Royal Institution during September 25–27. It consisted of six sessions devoted to various aspects of desert biology: climate and physical environment; plant ecology; entomology and ecology; economic aspects; and mammalian physiology and ecology.

Dr. Edward Hindle, president of the Institute, in an opening speech in which he welcomed delegates from abroad, mentioned that the United Nations Educational, Scientific and Cultural Organization showed a special interest in the symposium and contributed towards the expenses of speakers from overseas. Brigadier R. A. Bagnold (the well-known desert explorer) then communicated an introductory paper on the geography of deserts by Prof. Frank Debenham (formerly professor of geography in the University of Cambridge), who was not able to attend in person, and read his own paper on the physical aspects of dry deserts. In the first of these papers, it was pointed out that the distribution of deserts in the world is due mainly to the circulation of the atmosphere, particularly in its lower layers, whereby certain areas are starved of moisture. In addition, many local factors affect the intensity of desert conditions, and excessive insolation by day tends to produce extreme instability in the rainfall. Brigadier Bagnold then said that this intermittent precipitation is variable not only in time but also in place, and only by nomadic wandering over large areas can its effect be exploited. If nomadism were prevented for political reasons, much of the desert would become totally unproductive. Prof. F. W. Shotton (University of Birmingham) emphasized the salinity of most underground desert waters, which are consequently unsuitable for irrigation. Although in semi-desert areas such as southern Palestine considerable development of underground waters can still be hoped for, the prospect for the greater part of the true deserts must always be poor. Dr. C. B. Williams (Rothamsted Experimental Station) then described three studies of microclimatic conditions made some years ago at Wadi Digla in the hilly desert near Cairo. Great variations in conditions occurred between localities only a few feet apart, particularly during the summer; but twelve metres within a cave the daily and seasonal range of temperature was only 2 deg. C. Thus by moving a very short distance, animals can escape extremes of heat and have a wide range of conditions at their disposal. In the discussion that followed, Prof. J. A. Prescott (Waite Agricultural Research Institute and University of Adelaide) pointed out that the variable and local nature of the rainfall in northern Australia has long been realized by pastoralists whose cattle, unhindered by fences, travel great distances to favourable areas. and Dr. H. Greene (Rothamsted Experimental Station) suggested that, although the violent spates of water in the wadis of the Sudan carry so much sediment that storage by dams is impracticable, the deposition of this as silt results in a natural rotation of the soil.

Dr. Hugo Boyko (chief ecologist to the Ministry of Agriculture, Israel) opened the second session with an account of the main lines of plant ecological research that are being carried out in his country. These include pasture problems and the effect of grazing, searching for food plants adapted to desert conditions and for plant raw materials, and the application to biology of other branches of science such as climatology, hydrology and hydro-engineering. A paper by Prof. Th. Monod (director of the Institut Français d'Afrique Noire) outlined the distribution of the basic contracted and diffuse types of vegetation in the Sahara, and Prof. R. D'O. Good (University College, Hull) gave an account of the desert flora of the arid Bahrain Islands in the Persian Gulf. These islands are of interest in that they illustrate with peculiar clarity, and within a circumscribed area, many of the characteristic features of deserts in general. Prof. M. Zohary (Hebrew University, Jerusalem) then presented an analysis of the many hydro-economic types of vegetation occurring in the Near East deserts, and a paper by Prof. I. Reichart (Jerusalem), crediting xerothermic climates with the suppression of many pathogenic bacteria and downy mildews, was followed by a general discussion.

In the third session an exposition of phyto-sociological research carried out in French North Africa to provide a rational basis for the evaluation of the soil was given by Prof. L. Emberger (Montpellier). At Montpellier and Zurich a cartographical method has been devised to demonstrate vegetational associations which directly indicate the nature of the underlying rock, and similar surveys are now being carried out in central Tunisia and western Algeria. The secretary-general of the International Union of Biological Sciences, Prof. P. E. L. Vayssière, then described how modern methods of rapid travel have, in a number of cases, transported pests of such economic plants as dates and cotton across natural barriers of arid desert, and introduced them into oases and other areas from which they had previously been absent. Dr. B. P. Uvarov (director of the Anti-Locust Research Centre, London) gave a warning that desert irrigation schemes may increase the danger of locust infestation in other areas by providing new permanent breeding-grounds. The desert locust requires adequate soil moisture before it can increase in numbers to the point of swarming, and, both at Abyan near Aden and at Tokr on the Sudan coast, irrigation schemes have already resulted in a semi-permanent population of desert locusts. Dr. A. S. Balachowsky (Institut Pasteur) gave an account of the problems of applied entomology in the Sahara, with particular reference to the biology of indigenous species that have become adapted to feed upon cultivated plants. This was followed by a description by Prof. F. Bernard (Algiers) of the economic importance of social insects, particularly termites and ants, in the desert. Methods were suggested for encouraging useful, and for reducing harmful, species.

The microbiological formation of sulphur in Cyrenaican lakes, particularly Ain-ez-Zaua, was the subject of a joint paper by K. R. Butlin and J. R. Postgate, who led an expedition from the Chemical Research Laboratory, Teddington, to the area in 1950, and methods of increasing the yield were discussed. Prof. E. P. Stebbing (formerly professor of forestry in the University of Edinburgh) emphasized that the man-made desert is a stern reality ; man has been the enemy of forests since earliest times, and large-scale clearing has resulted in erosion and the production of arid regions. Dr. S. M. Manton (King's College, London) then gave an outline of the large irrigation and development schemes being carried out in Central Asia, and of the biological research associated with the construction of the Turkmenian canal and the development of the Kara Kum desert. She was followed by Prof. J. F. V. Phillips (Achimota, Gold Coast), who discussed aspects of the ecology and productivity of the arid regions in southern and eastern Africa. The deserts themselves are of little potential productive importance, but their significance in regard to possible encroachment is profound. Mismanagement by most African and many European farmers, he said, is increasing the desiccation of the land at an alarming rate. Emphasis was laid on the role of the tsetse fly in controlling too rapid a development and on the agencies responsible for increased erosion. From experience gained while associated with the Groundnuts Scheme, Prof. Phillips gave warning of the far-reaching repercussions of insufficiently planned attempts to clear large areas of natural vegetation within a short time, and advocated ecological surveys and pilot schemes extending over at least five years. In the discussion that followed, the damaging effect of clearing forest by fire was contested by Dr. A. S. Thomas (London).

Sessions on the last day were devoted to problems of mammalian physiology and ecology. Prof. F. S. Bodenheimer (Hebrew University, Jerusalem) described research on the seasonal cycle of the gonads and endocrine glands in gazelles and camels, carried out in his laboratory at Jerusalem. This cycle is adapted to the seasonal rainfall, with the result that the young are born when vegetation is most abundant. Dr. Norman C. Wright (scientific adviser to the Ministry of Food) compared the morphology of domesticated animals inhabiting hot and cold deserts, in contrast to that of animals from non-desert areas. The majority of the former are slightly sweating species that employ polypnea as a temperature defence mechanism. Solar radiation is reduced by various protective devices which were discussed from the point of view of the histology of the skin, the hair characteristics and behaviour reactions. Suitable fodder may help to alleviate the gross heat burden. Water conservation in kangaroo-rats and pocket mice was discussed by Dr. Bodil Schmidt-Nielsen (Cincinnati), who has investigated the physiology of the desert rodents in Arizona. She found that these animals never drink, but obtain an amount of water equal to more than half the weight of the dry seeds which form their staple diet by oxidizing this food within their bodies. Evaporation from the respiratory tract is relatively small because of the low temperature of the respired air, the urine is very concentrated and the fæces contain less water than that of most mammals. The subject of heat regulation in these animals was mentioned by Dr. Knut Schmidt-Nielsen, who said that the loss of water by evaporation is avoided by living in burrows during the day and emerging only at night. If a kangaroo-rat is exposed to great heat, the fur of its throat becomes moistened with saliva, but even by this means it cannot survive for more than twenty minutes. Although the areas covered by bluebush in southern Australia have been greatly depleted during the past century, Prof. H. C. Trumble and Mr. K. Woodroffe (University of Adelaide) found that properly controlled grazing, pruning of older bushes and seedling establishment by reduction of competition for moisture from annual species could induce a general improvement. Problems of water conservation and of adaptive coloration formed the principal topics of the discussion which followed.

In the final session, Dr. J. S. Weiner (Oxford) discussed human adaptability to high temperatures and suggested that the function of the skin pigment in the Negro is primarily to protect the sweat glands from injury by excessive ultra-violet light. Dr. Frank Marsh (London) then described experiments on rabbits subjected to great environmental heat, which threw light on the treatment of human heat-stroke, and a paper was given by Dr. Edmond Sergent (director of the Institut Pasteur d'Algérie) on the problems of populating the Sahara: he postulated that white families could never become acclimatized there as the heat is too great for the women and children, black races would find the winters too cold, and the nomads, who are camel owners, shepherds and warriors, are useless at manual work; consequently, only the indigenous negroid race could usefully multiply, and only in proportion to the amount of water available. Dr. O. G. Edholm (London) described the physiological effects of cold environment on man. He said that although acclimatization to cold occurs, it is a relatively slow process, and suggested that, in fact, man has probably evolved as a tropical animal. Sir David Brunt (formerly of the Imperial College of Science and Technology) showed by means of graphs the conditions in which office work can be carried on in the afternoon in tropical climates. The limitation appears to fall within a well-defined range of temperature and humidity.

After the discussion, Dr. Frank Malina spoke on behalf of Unesco, and Prof. J. F. Danielli (King's College, London), honorary secretary of the Institute of Biology, summed up. The latter said that, from the papers presented at the symposium, it was apparent that individual deserts present a multitude of different problems. Scientific investigation must precede development; but in most cases the major difficulties are social, moral and political, and present problems of ethics rather than of science.

The proceedings of the symposium will be published by the Institute of Biology, Tavistock House South, W.C.1. Prof. R. D'O. Good has very kindly read through this article in manuscript.

J. L. CLOUDSLEY-THOMPSON

NEWS and VIEWS

Mechanical Engineering in Manchester: Prof. Jack Diamond

THE Council of the University of Manchester has announced the appointment of Mr. Jack Diamond to the first chair of mechanical engineering in the Faculty of Science. This is additional to the Beyer chair (founded in 1868 and first held by Osborne Reynolds) and the chair of electro-technics (1912). In addition there are also, in the Faculty of Technology, chairs in both mechanical and electrical engineering, established when that Faculty was established in the Manchester College of Technology in 1905.

Mr. Diamond's early training was followed by an apprenticeship at H.M. Dockyard School, Chatham, from which he proceeded to the City and Guilds College, London, as a Whitworth Scholar in 1932. In 1935 he was awarded first-class honours in mechanical engineering and was elected to a Senior Whitworth Scholarship. This he held for the next two years at St. John's College, Cambridge, where he undertook research in heat transfer; he was awarded the degree of M.Sc. in 1937. Mr. Diamond was then appointed a demonstrator in mechanical sciences in the University of Cambridge and a supervisor in St. John's College, resigning in 1939 on taking a temporary commission as an engineer officer in the Royal Navy. Three years later he was appointed assistant to the Engineer Manager of Rosyth Dockyard and, after becoming a temporary lieutenant-commander (E.), retired from the service in 1944 to become a senior scientific officer in the British Atomic Energy Team at Montreal. Since 1946, he has been a senior principal scientific officer at the Atomic Energy Research Establishment at Harwell, working on the design and development of nuclear reactors and on associated heat-transfer problems.

Seventieth Birthday Anniversaries: Profs. J. Franck and M. Born

ON August 26, 1952, Prof. James Franck, the director of the Fels Fund research in the University of Chicago, and formerly of Gottingen and the Johns Hopkins University, celebrated his seventieth birthday. A tribute in honour of his birthday appears in the July number of the *Reviews of Modern Physics* (24, 117; 1952). It is contributed by Prof. Peter Pringsheim, of the Argonne National Laboratory, Chicago, and consists of a short biographical article describing briefly Franck's numerous scientific achievements. Born in Hamburg, Franck studied chemistry in Hamburg and Berlin, and was appointed in 1920 to the chair of physics at Gottingen. During the thirteen years that followed, Gottingen became under Franck's direction one of the most important centres of research in atomic and molecular physics, a happy and brilliant period which was brought to an abrupt end when Hitler assumed power in Germany. Throughout his whole career, Prof. Franck's work has been characterized by a simplicity in experimental apparatus and principle: the well-known Franck–Condon principle is but an application of the law of conservation of momentum, and the Franck–Hertz experiment of 1914, for which Franck obtained the Nobel Prize a few years later, was a straightforward experimental confirmation of Bohr's atomic theory. The study of fluorescence has been Franck's main occupation, and from that he has been led more recently into the important field of research in photosynthesis. Finally, Prof. Pringsheim singles out for special mention Franck's two outstanding qualities, his obsession for science and his inexhaustible kindness. As a further tribute and one emanating from Gottingen itself, Profs. M. von Laue and R. W. Pohl, the editors of the *Zeitschrift für Physik*, have collected together in the number for September 15 (133, 1; 1952) a series of articles specially contributed by colleagues and friends of Prof. Franck and of Prof. Max Born, of the University of Edinburgh, who also celebrates his seventieth birthday this year, on December 11. Most of the articles are in German, but several are in English.

The Pharmaceutical Society: Hanbury Memorial Medal

THE Pharmaceutical Society has awarded the Hanbury Memorial Medal to Prof. Gösta Edman, professor of botany and pharmacognosy in the Royal Pharmaceutical Institute, Stockholm. This Medal is given periodically for "high excellence in the prosecution or promotion of original research in the Natural

History and Chemistry of Drugs". Prof. Edman's investigations have dealt with several aspects of drugs of vegetable origin. These include studies of the ash content and the presence of silica in drugs and the application of chemomicroscopical tests. His numerous microscopical studies of structure have been directed towards the discovery of adulteration, and to the identification and standardization by structural characters of crude vegetable drugs both in the unground condition and in the form of powder. The Medal will be presented at a meeting of the Society on February 9, when Prof. Edman will give an address entitled "Ash Pictures in the Identification and Assay of Vegetable Drugs".

American Academy of Arts and Sciences: Rumford Medals

RUMFORD MEDALS of the American Academy of Arts and Sciences have been awarded to the following: Prof. Enrico Fermi, of the University of Chicago, for his studies of radiation theory and nuclear energy; Prof. Willis Eugene Lamb, jun., of Stanford University, for his studies of the atomic hydrogen spectrum; and Prof. Lars Onsager, of Yale University, for his contribution to the thermodynamics of irreversible flow. The bicentenary of the birth of Benjamin Thompson, Count Rumford, will be celebrated by the Academy in Boston during March 26–28, 1953, when the Medals will be presented and conferences arranged on the fields of science represented by the recipients. Rumford was born at Woburn, Mass., now a suburb of Boston, on March 26, 1753, and in 1796 he gave a fund to the Academy to be used for the awarding of gold and silver medals to encourage scientific investigations in the field of heat and light. To date forty-eight Rumford Medals have been awarded.

American Section of the Society of Chemical Industry: Perkin Medal

THE American Section of the Society of Chemical Industry has awarded the Perkin Medal for 1953 to Dr. Charles Allen Thomas, president of Monsanto Chemical Co., St. Louis, and chairman of the board of directors of the American Chemical Society. The Perkin Medal, of which this is the forty-seventh award, is given for outstanding achievements in applied chemistry and was founded in 1906, being first awarded to Sir William Henry Perkin in commemoration of the fiftieth anniversary of his synthesis of mauve, the first synthetic dye. Dr. Thomas has made outstanding contributions to many phases of industrial chemical development—including the atomic energy programme; several phases of the pioneer development and general utilization of anti-knock, high compression fuels for internal combustion engines; important contributions to knowledge of the chemical reactions of hydrocarbons in the presence of catalysts, particularly aluminium chloride; synthesis of resins and other useful products from petroleum and its by-products; and fire-fighting devices and methods—as well as for his leadership in both the profession and industry of chemistry.

Sheep Biology Laboratory, Prospect, New South Wales

A NEW Sheep Biology Laboratory has recently been set up at Prospect, near Parramatta, New South Wales, by the Commonwealth Scientific and Industrial Research Organization, and Prof. C. W. Emmens has been appointed as officer-in-charge. Prof. Emmens has a distinguished record as an animal physiologist and was for many years engaged on research at the National Institute for Medical Research, London; concurrent with his new post, he will continue his present work as professor of veterinary physiology in the University of Sydney. The Prospect Laboratory will concentrate on problems of fertility and reproduction, the physiology of wool production, and sheep breeding and genetics, and it is hoped eventually to build it up as a leading world centre of information on all scientific data relating to sheep and wool husbandry, particularly the Merino and other types specially evolved in Australia. A balanced programme of both laboratory studies and field investigation is planned to develop the potentialities of healthy sheep in terms of quality and quantity of fleece, higher lambing percentages and the breeding of specialized types. Linked with the central Laboratory will be a series of sheep and wool field-stations in the major wool-producing regions, equipped to study all relevant aspects of soils, pastures, animal husbandry, disease control and plant and animal management. The Laboratory is being established on an area of 130 acres which has been carefully selected to provide good potential for pasture management and improvement and space for the cultivation of fodder crops. The full building programme will not be complete for some time, but sufficient laboratory accommodation and animal houses, feed stores, fleece and shearing sheds are now available in prefabricated buildings to enable research to be started.

Abstracting Board of the International Council of Scientific Unions

THE International Council of Scientific Unions has set up an Abstracting Board (Bureau des Résumés Analytiques du C.I.U.S.) with the purpose of facilitating the work of existing well-established journals publishing abstracts of original papers in the field of the natural sciences (see p. 960). A beginning has been made in the field of physics, and two member journals, *Physics Abstracts* and the *Bulletin Analytique*, are represented on the Board. In principle, any journal can seek membership to the Board, which is constituted, under a neutral chairman, of representatives of the interested International Unions and representatives of the member journals, together with the secretary-general of the Council as an *ex-officio* member. The present constitution of the Board is as follows: *Chairman*, Dr. Verner W. Clapp (assistant librarian, Library of Congress); *Secretary*, Prof. G. A. Boutry (Paris); *Members*, Dean Elmer Hutchisson (Case Institute of Technology), representing the International Union of Pure and Applied Physics, Dr. J. H. Ashery, representing *Science Abstracts*, Dr. G. Kersaint, representing *Bulletin Analytique*, Prof. A. V. Hill (secretary-general of the International Council of Scientific Unions). Dr. L. H. Lampitt sits as an observer for the International Union of Pure and Applied Chemistry. The offices of the secretariat are at the Institut d'Optique, 3 Boulevard Pasteur, Paris 15e, where work has already begun with the aid of a special subvention from Unesco. The secretary of the Board will gladly give any information desired about the facilities which can be extended to member journals.

Preservation of the Peak District

THE annual report for the year up to May 1952 of the Sheffield and Peak District Branch of the Council for the Preservation of Rural England (pp.

28; from the honorary secretary, Mrs. Gerald Haythornthwaite, Endcliffe Vale House, Sheffield 10; 1952), after expressing disappointment that the Government's nominees on the Joint Board for the Peak District National Park should include so few with knowledge and experience of rural preservation in the region, stresses the major threat to the Peak constituted by the unlimited demands of the limestone industries to encroach upon the National Park. The Joint Board has adopted the policy that, while quarrying in the Park cannot be excluded, demands should receive the closest scrutiny; but the Joint Committee for the Peak District National Park considers that, in view of proposals to demolish Eldon Hill and to extend the Tunstead Quarries eastward so as to destroy Meadow, Wormhill and ultimately the exquisite series of dales from Peak Forest to Millersdale, the time has come to make a stand for the very existence of the Park and of the Peak. Open-cast coal-mining still constitutes a threat at Wentworth Woodhouse and in the Cordwell valley, and East Derbyshire continues to lose farmlands and woods at a disastrous rate. Action has also been necessary in regard to Sheffield's Green Belt, on which housing proposals threatened encroachment, as does the Sheffield Development Plan, which fails to indicate Green Belt land as such. In conjunction with the Don Valley Amenities Society, steps have been taken to restore the lost beauty of this Valley, and the first hardwood trees of the Wharncliffe State Forest were planted during November 1951. In spite of protests, the Government has approved the use by the War Department as a training-area and mortar-range of 2,700 acres north of Upper Hulme and west of Staffordshire Roaches in one of the wildest parts of the National Park, and this is a serious loss to amenity.

Journal of the Mechanics and Physics of Solids

The first number of a new periodical entitled *Journal of the Mechanics and Physics of Solids* (1, No. 1, pp. 76; 90s. per vol. (4 Nos. per vol.); London: Pergamon Press, Ltd.) appeared in October under the joint editorship of Dr. R. Hill, of the University of Bristol, and Prof. W. M. Baldwin, jun., of the Case Institute of Technology, United States. The setting-up of this journal, under a distinguished advisory board, marks a further step in the emergence of studies of solid deformation from the general wide background of physics, mathematics, physical chemistry and metallurgy. The process has been detectable for some years, and notably so since 1945, during which time a vigorous development in solid-state physics, strongly led by physicists in Great Britain and in the United States, has transformed the whole approach to the mechanics of crystals. During these years, the same fundamental problem of elucidating the mechanisms of the deformation of materials and aggregates of various kinds, both metallic and non-metallic, has engaged the attention of research workers in every branch of pure and applied science, and the result of these researches is scattered throughout the literature. The more general that deformation phenomena and theories are discovered to be, the greater does the need become for some common channel of expression. There certainly exists, then, a strong reader-demand for a publication on these lines. As for the writer of research papers, it may be said that the subject with which this new journal is concerned had grown far too large for the journals that already existed. Further, and quite simply, the subject is worthy of a journal of its own. It is clearly not the concern of a publication devoted in the main to fundamental research (and this would appear to be the case to judge from the first issue) to seek any sort of justification for its activities on practical grounds; fundamental research is its own justification. Yet those concerned with the technological development of modern machines (the word is used in its widest sense) know well that the old materials have been exploited to the limit, and far beyond the limit, and that the primary barrier to advance is not the design of successful machines, but their fabrication, for present materials cannot contain them. The importance of the subject is thus in no doubt. Pure and applied science will surely welcome the appearance of this new journal as both timely and valuable.

Fiftieth Volume of the *Journal of the Bombay Natural History Society*

On September 15, 1883, five Scotsmen, one Englishman and two Indians met in Bombay and formed a society for the study of natural history, and this was the beginning of the Bombay Natural History Society. Three years later, though the membership was still small and confined to the residents in or near Bombay, the Society decided on the bold step of starting a journal. At this time there was only one periodical in India—the *Journal of the Asiatic Society of Bengal*—for the publication of papers on zoology and botany, and these, as a rule, of a strictly scientific character. The aim of the editors of the Bombay *Journal* has always been to publish not only scientific papers but also articles of a more popular character, and at the same time to encourage members to contribute short notes on any subjects of interest. How successful they have been is shown by the long series of volumes—the fiftieth of which has now been issued (50, No. 4; from the Society, 114 Apollo Street, Bombay). Many of the volumes run into more than a thousand pages and contain papers of great importance by specialists as well as popular articles such as "A Popular Treatise on the Common Indian Snakes", and the "Beautiful Flowering Trees of India", while the short notes from members have thrown much light on the distribution, etc., of both plants and animals. Though in the main the contributions to the *Journal* have dealt with the fauna and flora of India, Burma and Ceylon, there have also been a few on countries beyond these boundaries, such as "A Survey of the Fauna of Iraq" started during the First World War. At one time the membership of the Society numbered more than two thousand, and copies of the *Journal* were in practically every club and mess in India. Since 1947 the membership has decreased, but the standard of the *Journal* is as high as ever; and for this the editors are to be congratulated.

A Diffusion Reaction Theory of Morphogenesis

In a recent publication, "The Chemical Basis of Morphogenesis" (*Phil. Trans. Roy. Soc.*, B, 237, 37; 1952), Dr. A. M. Turing has advanced the theory that a system of chemical substances, described as morphogens, reacting together and diffusing through a tissue, may account adequately for some of the main phenomena of morphogenesis in plants and animals. The biochemical system in an embryonic tissue, envisaged as being initially quite homogeneous, that is, with a homogeneous distribution on the morphogens, may be 'triggered off' by some random disturbance ; the system then becomes unstable, the distribution of the morphogens becomes heterogeneous and later a pattern or structure may develop. Such diffusion reaction systems are considered in the hypothetical case of a ring of cells. Using the digital computer, Turing has shown that in such a system the onset of instability may take six different forms, of which the most interesting form, from the point of view of morphogenesis, consists in the development of stationary waves on the ring. This would be equivalent to the accumulation of one of the morphogens at evenly distributed points on the ring, and might account for such developments as the tentacle pattern in *Hydra* and for whorled phyllotaxis and similar phenomena in plants. A system of reactions and diffusion on a sphere, which is also considered, could account for gastrulation, while another reaction system in two dimensions yields patterns resembling dappling. There are also indications that stationary waves in two dimensions may account for phyllotaxis. Basically the theory does not involve any new hypotheses ; but, assuming a gene-controlled metabolic system, it suggests that certain well-known physical laws are sufficient to account for many of the facts of morphogenesis.

Plant Raw Materials

The new botanical journal, *Materiæ Vegetabiles* (editors, Drs. C. Regel and Fr. Tobler ; published by Dr. W. Junk, The Hague), of which the first number has just been issued, is essentially utilitarian in its aims. The journal, in fact, "will be dedicated to the whole domain of vegetable raw materials", and it will contain papers in which research, cultivation, extraction, amelioration, preparation and utilization are treated in their mutual relationships. The literature of plant products appears either in book-form or widely scattered in botanical, agricultural, technical, chemical and trade journals. The new journal will provide a means of bringing these important practical contributions together under one cover, and by so doing should make for a stimulation of research into the better production and wider utilization of plant products. The present number includes papers on such diverse topics as the value of Karoo veld in stock raising, flax as an oil and fibre plant in La Plata territory, the scientific basis of improved rosin production, cæsalpinias as sources of tannin, the effect of manuring on fibre content in *Yucca*, the significance of terpene accumulation in plants, and the utilization of fibre from the stems of edible bananas. The subscription for the volume of four numbers is 40 Dutch guilders.

Library of the National Institute for Research in Dairying, Shinfield

No. 4 in the Library Association series of pamphlets, "The Development and Administration of a Special Library", by C. H. Tomalin, is an account of the Library of the National Institute for Research in Dairying, Shinfield, Reading (pp. 36 ; 1951. 5*s*. or 3*s*. 6*d*. to members). It gives a brief account of the present stock of the Library and of the administrative methods in use, as well as of the development of the Library from the founding of the Institute until the new Library building was opened in October 1934. Primarily the Library exists to serve the scientific staff of the Institute; but it is also much used by scientific workers visiting the Institute. A card index is maintained which records all significant papers in dairy research published since 1920.

Symposium on Food Supplies

The Nutrition Panel of the Food Group of the Society of Chemical Industry is arranging an extended symposium on "Food and the Future", which will be discussed at a series of four meetings, to be held during the period December 1952–April 1953, when the topics will be, respectively : the problem of future world food supply ; present methods of attack on the problem ; new natural sources of foodstuffs ; and synthetic food potentialities. At the end of the series, Dr. Norman C. Wright, scientific adviser to the Ministry of Food, will sum up the discussions. The first of these meetings will be held in the rooms of the Chemical Society at Burlington House, Piccadilly, London, W.1, at 6.15 p.m., on December 10, when Mr. F. Le Gros Clark will deal with a general statement of the problem of future world food supply under the title "The Yardstick of Population", and Dr. E. W. Russell will consider "Limitations affecting the World Food Supply". Visitors will be welcome. The honorary secretary of the Panel is L. C. Dutton, Virol, Ltd., Hanger Lane, Ealing, London, W.5.

Announcements

H.R.H. The Duke of Edinburgh has accepted election to honorary membership of the Institution of Mining and Metallurgy and also of the Institution of Gas Engineers.

Dr. G. R. de Beer, director of the British Museum (Natural History), has been elected *correspondant* of the Section of Anatomy and Zoology of the Paris Academy of Sciences in succession to the late T. O. J. Mortensen.

The following appointments have recently been made in the University of Sheffield : Dr. J. White, senior lecturer in refractories, to be reader in ceramics ; Dr. A. S. Gladwin, to be lecturer in electrical engineering.

The following announcements have been made from the University of London : the title of reader in mechanical engineering applied to mining in the University has been conferred on Dr. William Davies, in respect of the post held by him at the Imperial College of Science and Technology ; the degree of D.Sc. has been conferred on Mr. Dan Lewis, an internal student at the John Innes Horticultural Institution.

The Textile Institute, under the terms of the Cotton Industry War Memorial Trust, awards scholarships to young craftsmen in the cotton industry, which are designed to cover the cost of a three-year full-time university degree-course in textiles. Two such awards have just been made, to N. Clark (Stalybridge, Cheshire) and R. M. Watson (Manchester), respectively, both of whom have elected to go to the Faculty of Technology of the University of Manchester. This scholarship scheme was started in 1930, and to date ten awards have been made.

The annual conference of the Geographical Association will be held at the London School of Economics, Houghton Street, London, W.C.2, during December 31, 1952–January 3, 1953. The programme will include business meetings, lectures, discussions, reports and special visits to places of interest. There will also be exhibitions by the various sections of the Association and displays of books, visual aids and other educational equipment. Further information can be obtained from the honorary conference organizer, Dr. W. G. V. Balchin, of King's College, Strand, London, W.C.2.

THE PLACE OF THE SCIENTIST IN CIVIL DEFENCE

ON the evening of October 16, the London and South-Eastern Counties Section of the Royal Institute of Chemistry, the London and Home Counties Branch of the Institute of Physics and the Institute of Biology met in the City of London School to discuss the place of the scientist in civil defence. Speaking from the chair, Dr. C. W. Herd, chairman of the local section of the Royal Institute of Chemistry, said the meeting had been arranged to enable members to state their views on the employment of scientists in civil defence, and, so that they might hear something from the official angle, he was glad to introduce the Director-General of Training and the Scientific Adviser to the Home Office and also the honorary scientific advisers from the London Civil Defence Region.

In outlining points which were causing anxiety, Dr. Herd said he would be expressing personal views; but these were based on many discussions with professional colleagues, so he thought they would be typical of the opinions of many members present. During the Second World War, there was a good deal of dissatisfaction over the status of gas identification officers in relation to other branches of civil defence. To-day he felt that official recognition of the professional standing of chemists, physicists and biologists recruited for technical reconnaissance was inadequate to enable the services of these officers to be utilized effectively. This resulted in a sense of frustration among the officers concerned and might even prevent some from offering their services. Senior technical reconnaissance officers should, in their special field, be recognized as competent advisers to civil defence controllers. At present, to be quite frank, he said, professional men ack confidence in the scientific side of civil defence at local-authority level, and this confidence must be built up if the scheme is to be a success.

After referring to other points which on present evidence seem unsatisfactory, Dr. Herd said he thought he duty of the technical reconnaissance officer should be first to the public, to inspire confidence and maintain morale; secondly, to the civil defence controller o advise on scientific and technical matters; thirdly, o direct technical reconnaissance; and, finally, to ollect scientific and technical information for transmission to regional advisers. He suggested that a enior technical reconnaissance officer should be free o gather around him all scientists in his district and o give them technical information and training, so hat there would be a pool of trained men available o deal with any emergency in addition to those fficially recruited to the headquarters establishment. Potential recruits should now be reassured regarding heir status in the corps and their method of recruitment, with full information of the nature of their uties and the amount of training they would have o undertake. Regarding training, they should not e expected to attend very elementary lectures on echnical subjects. Once in the corps, interest should e maintained through periodic meetings officially rganized to keep them up to date in their subjects. uch meetings should not be left to the initiative of he officers themselves as happened during 1939–45.

Prof. W. V. Mayneord, one of the London regional scientific advisers, said that scientists ought to remember they are all primarily citizens, so that many of their duties are the same as other members of the community, even though the highly technical nature of modern warfare throws a special responsibility upon them. The contribution a person could make to civil defence depends upon his general training, and a physicist's first approach to the problem should be in the direction of quantitative studies of the effects of weapons in different circumstances. Such work could help the scientists officially employed on this type of research. The first thing to remember about the atomic bomb is the fear of the unknown that such a weapon creates. The trained scientist should therefore make himself as well informed as possible on all aspects of the subject, so that he might win the confidence of the public and do valuable work by allaying unwarranted fears.

Prof. Mayneord then dealt with the technical aspects of an atomic explosion, pointing out that radiation effects, though of great scientific interest, are likely to be only of secondary importance in causing casualties. Existing knowledge could be used to assess the relative values of different materials in building structures as protection against the penetration of radiation. Similarly, knowledge of the dose required to produce specific effects could be used to determine the circumstances in which the civil defence services could work in complete safety or when, in emergency, a calculated risk might be deliberately accepted. The scientist could be of value in the training of non-technical people, especially in designing the form which such instruction should take, as this is most important. To sum up, the scientist in civil defence should make himself a competent adviser in whom his controller will have full confidence, and in reconnaissance work the aim should be accurate observation and reporting of significant facts followed by informed interpretation of this information, so that it could be quickly and effectively used in dealing with the tactical situation.

Prof. H. N. Rydon who, until his recent appointment to Manchester, was also one of the scientific advisers in the London Region, then discussed the nature and magnitude of the problems resulting from the use of biological and chemical warfare. By the end of the Second World War, a new group of chemical agents had been developed in Germany, namely, the nerve gases, the characteristics of which he then described, pointing out the high toxicity of some of these in both the liquid and vapour phases. A satisfactorily sensitive test for detection has been developed, and civil defence services will be provided with a vapour detector kit capable of identifying the vapour of either mustard gas or the nerve gases in the required concentrations. The technical reconnaissance officer will be responsible for gas detection in the field and for advice on any measures required to deal with the situation resulting from an attack with chemical agents. He must in addition always be on the look-out for unusual effects, for it cannot be assumed that new and even more toxic agents will not be discovered. Systematic study of the behaviour of war gases in cities would be of the greatest importance, for there is no practical experience of their use in such circumstances. The role of the trained chemist in collecting such data would be of great value to the scientists at regional and government headquarters, and would also be of value to the Armed Forces.

The effectiveness of biological warfare, Prof. Rydon said, is still unknown; but he thought the wild stories about a single bomb causing a widespread epidemic could be dismissed as fantastic. Comparatively little is yet known about the precise conditions required for initiating an epidemic; but it is known that to cause one deliberately at a selected time would be very difficult. Advances in the development of new drugs and antibiotics also reduce the possible choice of agents which might, even theoretically, be expected to achieve such an object. The standard of hygiene in modern organized communities is another factor which reduces the chances of epidemics being successfully initiated by attack from the air. Sabotage might perhaps remain a possibility; but this method would be localized in its effect and more amenable to control. If the epidemic idea be dismissed, biological warfare may be regarded as an exaggerated form of chemical warfare with agents having a toxicity greater than any of the war gases by a factor of tens; but against this the chances of people receiving an effective dose are probably reduced by a factor of a similar order. Biological warfare is a possibility with which civil defence must be prepared to deal; but there are still many problems connected with the choice of suitable agents and finding effective methods of using them, so that the chance of its success as a method of waging war may still be problematical. Whereas the potentialities of chemical warfare can be evaluated with fair accuracy, biological warfare is still an untried weapon.

In preparing to meet such threats, the services of trained chemists would be invaluable, and Prof. Rydon hoped that as a result of the meeting there would be a good response from chemists. The chemist could adequately perform many of the tasks connected with atomic and biological warfare as well as those in the chemical field, for his training puts him in a category intermediate between the physicist and the biologist. He hoped no one would withhold his services under the impression that civil defence is a purely passive function. The application of scientific advice could go a long way towards defeating an enemy's objective by minimizing the effects of his weapons, and this could at times be as important as the active operations of offensive warfare.

Sir John Hodsoll, director-general of training in the Civil Defence Department of the Home Office, said he could sympathize with what had been said about the Second World War, for some gas identification officers had undoubtedly been put in a difficult position; but it was hoped to benefit from the lessons which had been learnt. As to background, it was not intended that technical reconnaissance officers should take full basic training, and if this had occurred in some cases it must have been due to misunderstanding. In peace-time, scientists can make a valuable contribution by local studies designed to define the tactical problems resulting from different forms of attack.

In the civil defence organization there would be a chief reconnaissance officer at all control and sub-control centres, and he or his deputy would always be a technical reconnaissance officer, so that the controller would always have advice immediately available on the technical aspects of any problem. As regards recruitment, it is recognized that difficulties may have to be smoothed out in some cases; but it is in the local division that the technical reconnaissance officer is needed, so he must be part of the local organization. If success in any future war is to be achieved, civil defence services must be organized and trained now; for if the civilian population should give way a war would be lost even though the main military forces with all their equipment and resources still remained virtually intact. The real way to achieve this object is to see that knowledge of the right kind is available to all who should have it, and in this task the scientist can perform a most valuable work in creating the right attitude of mind among the general public.

The meeting was then thrown open for questions and general discussion, and many of the speakers elaborated the points made by the chairman in his opening address, particularly regarding the status of technical reconnaissance officers and their method of recruitment. Several speakers thought recruitment could be more effectively dealt with by making more use of the professional institutes. One speaker said that these particular difficulties are not universal, for, during the Second World War and again in the new arrangements, his relationship with his local authority was most satisfactory. Much emphasis was laid on the importance of giving scientific people the full technical details in all information furnished to them. A suggestion was made that an attack with biological agents after a heavy attack with high explosive might well produce an epidemic, since the standard of hygiene would be sub-normal and sanitation services would be disorganized. A question was asked about the arrangements for liaison with medical services, as some members feared that in certain circumstances difficulties were likely to arise. Another suggestion was made that radiotherapists, who had not apparently been considered for reconnaissance work, could be of value in the assessment of radiological hazards.

Sir Charles Ellis, senior scientific adviser in the London region, stressed the importance of the operational research approach to the type of problems which the technical reconnaissance officer would have to study. People trained to observe phenomena closely and to collate and interpret the data obtained could contribute a great deal to civil defence, and, whatever this type of work be called, such an officer should in effect be an operational research worker.

Dr. E. T. Paris, scientific adviser to the Home Office, in his summing up of the proceedings before answering some of the questions, said that the Home Office was much indebted to the three Institutes for organizing the meeting. Note would be taken of the points which had been made, and he was sure the discussion would be of value in further consideration of the problems involved. The need for scientists in civil defence had been clearly shown, as was confirmed by the discussion, since acceptance of the principle was implicit in the remarks of all speakers, however critical they might be on specific details.

The status of scientists in civil defence, Dr. Paris said, appears to be causing much anxiety. The position is that there are two distinct levels at which scientists are employed. The regional scientific advisers would assist the regional commissioners on all appropriate matters in each region, and in addition would have laboratory facilities and trained staffs for dealing with samples received from local authorities. On technical matters, they would work in direct collaboration with the Home Office and the appropriate Ministry of Supply research establishments. At the next level, the technical reconnaissance officers are in the headquarters section of the local division so that, as Sir John Hodsoll had explained, they are part of the local authority's organization and must in the long run be recruited through that machinery, though he would take note of the difficulties mentioned. The plea for full technical information was one with which every scientist would sympathize; though there is no secrecy in civil defence as such, it has to be recognized that information of a secret nature is used in the Home Office in the study of civil defence problems, so that it is not possible to pass on some kinds of information. From his own experience, he agreed with the principle that secret information should be given only to those who must have it in order to carry out their duties. He did not think there is any greater likelihood of an epidemic resulting from biological warfare attack after an attack with high explosives than in other circumstances. In any event it is necessary to guard against the tendency to conjure up complicated defence problems by piling one form of attack on another. A very great effort is required to deliver a modern attack on an effective scale, and any complication of the kind suggested must reduce the effectiveness of the first attack without greatly increasing the chance of the second attack being more effective than if it had been delivered alone on the appropriate scale.

Suggestions had been made about the possibility of the atomic bomb being 'played down' unjustifiably, and in particular a question was asked how this could be reconciled with the casualty figures published after the visit of the British Mission to Japan. There was no intention of minimizing the potentialities of the bomb; but what had been attempted was to show how the number of resultant casualties might vary in different circumstances. For example, if it was assumed that an unwarned attack on a city with the population all exposed in the open would result in, say, 50,000 casualties, then it could be shown that if everybody was in houses of an assumed standard of construction the casualties would be reduced to 30,000 under the same attack; and again, if they were all in special shelters of a specified standard of protection, the casualties would fall to 10,000.

In conclusion, Dr. Paris said the discussion had served a most useful purpose in providing evidence of the kind of difficulties that might arise in setting up the reconnaissance service, and of the lines on which interested scientists were thinking on these matters. Since the meeting, he has agreed to consider the problem in consultation with the three Institutes which organized the discussion. J. W. MARTIN

THE ALEMBIC CLUB

By PROF. JAMES KENDALL, F.R.S.

ON October 29, 1889, the five non-professorial members of the teaching staff of the Chemistry Department in the University of Edinburgh formed themselves, under the title of "The Alembic Club", into "an unassuming body which was destined later to play a useful part in bringing historical material connected with chemistry within the reach of interested readers". In order of seniority, the original members of the Club were:

1. John Gibson. The originator, with Prof. Crum Brown, of the famous Crum Brown–Gibson rule for determining the position of radicals entering a substituted benzene nucleus. Professor of chemistry in the Heriot-Watt College, Edinburgh, 1892. Died in 1914.

2. Leonard Dobbin. Distinguished for his research work in the history of chemistry and for his translations of Ladenburg's "Lectures on the History of the Development of Chemistry since the time of Lavoisier" (1900) and Scheele's "Collected Papers" (from Swedish and German originals, 1931). He was lecturer in chemistry in the University of Edinburgh, 1914; reader, 1920. Dr. Dobbin died in March 1952 in his ninety-fourth year. For seventy-one years he was a Fellow of the Royal Society of Edinburgh (Member of Council 1904–7 and 1913–16, Curator 1934–39, Vice-president 1939–42) and for more than sixty years a Fellow of the Chemical Society and the Society of Chemical Industry. Secretary of the Alembic Club from its inception to 1946, he was its guiding spirit throughout that long period.

3. Hugh Marshall. Discoverer of the persulphates: elected a Fellow of the Royal Society in 1904. After holding a lectureship in crystallography in the University of Edinburgh, he was appointed to the chair of chemistry in University College, Dundee, in 1908; he died in 1913.

4. James Walker. For many years the leading physical chemist of Great Britain. Professor of chemistry in University College, Dundee, 1894–1908, and in the University of Edinburgh, 1908–28. He was awarded the Davy Medal of the Royal Society in 1926, and the Gunning Victoria Jubilee Prize of the Royal Society of Edinburgh in 1932. President of the Chemical Society, 1921–23. Knighted in 1921 and died in 1935.

5. Alexander Smith. Famous for his research work on the allotropic forms of sulphur and for his series of text-books on inorganic and physical chemistry. Professor of chemistry in Wabash College, Indiana, 1890–94, in the University of Chicago 1894–1911, and head of the department of chemistry in Columbia University, New York, 1911–20. President of the American Chemical Society, 1911. Died in 1922.

Members elected afterwards were:

6. Ralph Stockman (1891). Professor of materia medica in the University of Glasgow, 1897–1936. Elected a Fellow of the Royal Society in 1889. Vice-President of the Royal Society of Edinburgh, 1939–42. Died in 1946.

7. James Kendall (1929). Professor of chemistry in Columbia University, 1914–26, in New York University, 1926–28, and in the University of Edinburgh, 1928 to date. Secretary of the Alembic Club since 1946.

8. Irvine Masson (1932). Professor of chemistry, University of Durham, 1924–38; vice-chancellor of the University of Sheffield, 1938–52. Knighted in 1950.

9. Oswald James Walker (1937). Formerly lecturer in chemistry, University College, London, now on the staff of Imperial Chemical Industries, Ltd. (Plastics Division), Welwyn Garden City.

At a very early stage in the existence of the Club, the important resolve was taken to publish some of the less easily accessible chemical classics in convenient form, as simple reprints (if in English) or as translations (if in a foreign language). It was fitting that the first of these "Alembic Club Reprints" should present in 1893 Joseph Black's world-renowned "Experiments on Magnesia Alba, etc.", in view of the author's occupancy for many years of the chair of chemistry in the University of Edinburgh. Succeeding reprints were: (2) "Foundations of the Atomic Theory", by Dalton, Wollaston and Thomson; (3) "Experiments on Air", by Cavendish; (4) "Foundations of the Molecular Theory", by Dalton, Gay-Lussac and Avogadro; (5) "Extracts from Micrographia", by Hooke; (6) "The Decomposition of the Alkalis and Alkaline Earths", by Davy; (7) "The Discovery of Oxygen", Part I, by Priestley; (8) "The Discovery of Oxygen", Part II, by Scheele; (9) "The Elementary Nature of Chlorine", by Davy; (10) "Researches on the Arseniates, etc", by Graham; (11) "Essays of Jean Rey"; (12) "The Liquefaction of Gases", by Faraday; (13) "The Early History of Chlorine", by Scheele and others; (14) "The Molecular Asymmetry of Natural Organic Products", by Pasteur; (15) "The Electrolysis of Organic Compounds", by Kolbe; (16) "Papers on Etherification, etc". by Williamson; (17) "Medico-Physical Works", by Mayow; (18) "Sketch of a Course of Chemical Philosophy", by Cannizzaro; (19) "The Foundations of the Theory of Dilute Solutions", by Van't Hoff and Arrhenius; (20) "Prout's Hypothesis", by Prout, Stas and Marignac; and (21) "On a New Chemical Theory, etc.", by Couper.

These twenty-one "Alembic Club Reprints" have enjoyed a steady sale (totalling more than 32,000) throughout the decades, and have undoubtedly proved of inestimable service to teachers, students and research workers in the domain of historical chemistry. They are issued by the Club's agents—E. and S. Livingstone, Teviot Place, Edinburgh—at a price just above the cost of publication, profits being deliberately restricted to a point that will permit the periodic replenishment of stock as particular numbers near exhaustion. No. 17 only is now out of print, because of its special expense.

In the months immediately preceding his death, Dr. Dobbin—frail in body, but with mind alert and unimpaired—became apprehensive as to the future of the Alembic Club, and the present secretary knew that he was acting as Dr. Dobbin himself would have desired when, with the approval of the other two surviving members, he proposed to the Council of the Royal Society of Edinburgh that the Council should accept the entire assets of the Club and the responsibility for the continuance of its series of reprints. This offer was cordially accepted by the Council on July 7, 1952, the general opinion being expressed that it would appear desirable not only to continue the existing reprints but also to extend the series by new issues of a similar nature in chemistry and adjoining fields of science. A committee was appointed, consisting of the president, the general secretary and the treasurer, to submit recommendations for the administration of the "Alembic Club Fund" on a broader and firmer basis under the ægis of the Royal Society of Edinburgh.

Before the Club passed under new management, however, its members decided to add to their number Norman Feather, professor of natural philosophy in the University of Edinburgh, in the hope that a precedent would thus be established ensuring the perpetuity of the Alembic Club within the Society.

The report of the Committee, approved by the Council on October 27, 1952, contained in fact a clause recommending that the Alembic Club should persist as a self-perpetuating body, fortified by the inclusion of the senior officers of the Society. Other recommendations were that an Alembic Club Prize of £50 should be awarded to a distinguished historian of science quinquennially, provided funds for it were sufficient, and that Alembic Club Lectures should be delivered at unspecified intervals. The first of such lectures will be formally entitled the Leonard Dobbin Memorial Lecture.

INTERNATIONAL COUNCIL OF SCIENTIFIC UNIONS

GENERAL ASSEMBLY IN AMSTERDAM

THE sixth general assembly of the International Council of Scientific Unions was held in the rooms of the Koninklijke Nederlandse Akademie van Wetenschappen in Amsterdam during October 1–3. Twenty countries were represented. Prof. H. R. Kruyt, president of the Division of Sciences of the Academy and a former president of the Council, welcomed the assembly on behalf of the Academy. He spoke of the importance of the work of the Unions with their freedom to organize scientific discussions unhampered by administrative and political influences, and pointed out that he has a special regard for the Council, having attended every meeting since 1922.

The president of the Council, Prof. A. von Muralt (Switzerland), thanked Prof. Kruyt for his welcome and the Netherlands Academy for its hospitality and help in arranging the meeting. He explained how his three years experience as president have given him a great respect for the Council and some of its activities; joint commissions, symposia, support of laboratories of international standing and of established scientific services, all are of great value at the present time. The Council owes a great debt to the United Nations Educational, Scientific and Cultural Organization (Unesco) for its financial aid, and it is glad to help the Organization to carry out part of its task; Prof. Muralt also acknowledged the help given throughout by Prof. Pierre Auger (head of the Natural Sciences Division of Unesco) and his staff. International congresses have begun to grow too large, partly owing to the great increase in the number of scientific workers and the rapid growth of fresh branches of science, and the point is being reached where the present organization is becoming inadequate. One must not be too reluctant to see new Unions formed, but this must lead to difficulties in the co-ordination by a central body. There must come a time when some federal groups should be formed, intermediate between the Council and its individual Unions. He felt obliged to mention one activity of the Council, namely, the starting of an abstracting board to help in improving what has become in many sciences a difficult situation. A limit has been set at first to one subject—physics (see p. 954 of this issue). One result of improved co-ordination between existing abstracting journals has been a considerable speeding-up of the publication of abstracts.

After a tribute to the work of the Council and its Unions on the scientific side, Prof. Auger pointed out a gap between the purely scientific aspects and the financial and administrative ones. Those responsible for the latter side, he said, do not always understand the needs of those responsible for the former. One instance of this is the lack of sufficient representation of science in the national delegations to Unesco. Prof. Auger put forward a proposal, which would be followed up in 1953, to form a scientific advisory committee on international scientific problems, and he thought that this might fill the gap.

Four countries which had joined the International Council of Scientific Unions since the last general assembly were then welcomed by the president, namely, Israel, Thailand, Spain and the German Federal Republic.

The International Mathematical Union was admitted as a new adhering organization. It was reported that the executive board had accepted provisionally an application from the Union of Physiology, and had not accepted applications from International Unions of Biochemistry, Nutritional Sciences, Scientific Psychology, Scientific Study of Population, and Philosophy of Sciences. A discussion followed in the case of the Union of Biochemistry, and it was agreed to recommend the continuance of discussions between representatives of the Union and of the Section of Biochemistry of the Union of Chemistry in the hope that an agreed solution of the problem might be found; a member of the Council would be ready to assist in these discussions as an independent observer.

Certain changes of statutes were made: these included the creation of the post of treasurer, to lighten the task of the general secretary; the removal of the figure of the annual contribution due from countries and unions from the statutes (power was given to the general assembly to fix it for three years at a time); and a tightening of the conditions governing the admission of newly formed Unions.

A discussion took place on the plans for an International Geophysical Year in 1957–58, a successor to the International Polar Years of 1882 and 1932. On this occasion observations would be made not merely in polar regions but also in low latitudes. The proposal came originally from the Joint Commission on the Ionosphere, but it was supported by the Unions of Astronomy, Geodesy and Geophysics, Radio-Sciences, Physics and Geography; the World Meteorological Organization is also co-operating. A small co-ordinating committee has been formed and it will meet very shortly, its convener being Col. E. Herbays, general secretary of the International Scientific Radio Union. Countries adhering to the Council have been asked to form national committees which would carry out the programme once it has been formulated, and the steering committee will, in due course, be enlarged. Other countries outside the Council are also being approached. Proposals for a redetermination of the network of world longitudes in the year 1957–58 were referred to the committee for inclusion in the general scheme. There was general agreement that a few special problems should be tackled: this was better than an attempt to gather a mass of observational data. As an example, the morphology of magnetic and ionospheric storms was mentioned by Prof. Berkner as a suitable problem. The year 1957–58 was selected as being one near sunspot maximum.

The assembly decided to urge its national adhering bodies to press for greater scientific representation on the national delegations to Unesco, and it also asked delegates to press for support of two international agreements drawn up by Unesco, on the importation and on facilitation of circulation of educational, scientific and cultural materials.

It was agreed to sever connexion with the Committee on Science and Social Relations, which has become a Joint Commission with the International Council of Philosophy and Humanistic Studies. The interests of the Committee had tended to move over from the purely scientific to the human and social side. After a discussion on the activities of the International Abstracting Board, it was agreed that to avoid confusion it should be known as the "I.C.S.U. Abstracting Board" or the "Bureau des Résumés analytiques de C.U.I.S.".

Sir Harold Spencer Jones, the Astronomer Royal, expressed the thanks of the assembly to the president for his distinguished services—the grace, humour and firmness with which he had presided over their meetings during the past three years, and also to the retiring general secretary, Prof. F. J. M. Stratton (Great Britain) for his devoted labours on behalf of the Council over a period of fifteen years.

The bureau of the Council for the next three years was elected as follows: *President*, Prof. B. Lindblad (Sweden); *Retiring President*, Prof. A. von Muralt (Switzerland); *Vice-Presidents*, Prof. H. Solberg (Norway) and Col. E. Herbays (Belgium); *Treasurer*, Prof. W. Albert Noyes (United States); *Secretary General*, Prof. A. V. Hill (Great Britain); *Members*, Prof. J. Pérès (France) and N. Kameyama (Japan).

SEVENTEENTH INTERNATIONAL GEOGRAPHICAL CONGRESS, WASHINGTON, D.C.

SINCE 1871 an International Geographical Congress has been held normally every three or four years, during the past half-century under the auspices of a continuing body, the International Geographical Union. The seventeenth Congress was held in Washington, D.C., during August 7–16 and attracted a record number of approximately fifteen hundred participants. Of these, more than twelve hundred were in personal attendance, and despite the difficulties of travel and dollar shortages some five hundred delegates from overseas countries were present, including approximately fifty from Great Britain.

To enable visiting delegates to see as much as possible of the work of their American colleagues, a number of other meetings were arranged at convenient times.

This is the centenary year of the American Geographical Society in New York, and the Society held open house during August 4–6 at its delightful premises in Broadway at 156th Street. At a special meeting of the Society, visiting scientific workers were honoured, Mr. J. M. Wordie, president of St. John's College, Cambridge, and president of the Royal Geographical Society and leader of the British delegation, receiving the Daly Medal.

During August 6–7 the Association of American Geographers and the National Council of Geography Teachers met simultaneously in Washington, D.C., and their meetings and joint banquet were attended by many delegates.

The attendance of so many from overseas in the United States was made possible by a generous provision of travelling fellowships and grants, particularly from the Wallace W. Atwood Senior Fund, administered with great generosity by his widow and family. Many American universities had previously arranged visiting professorships or lectureships, and those who gathered at Washington had, in many cases, already spent some time in different parts of the United States.

Nearly all the meetings were held in the Statler Hotel, where facilities had been arranged for a magnificent display of maps from many countries. After the official welcome, the opening general assembly and the official reception on August 8, the general arrangement was to have concurrent section meetings in the morning, and in the afternoons to have concurrent meetings of those commissions which had been carrying on the work of the Union since the preceding Congress at Lisbon in 1949.

Certain broad topics of current world importance were considered by a series of symposia, and for all these important meetings simultaneous translations into French, Spanish and English were available. The symposium on tropical Africa, under the chairmanship of Prof. Derwent Whittlesey (Harvard University), reviewed the progress of investigations in both the east and west. The necessity for continued study of those factors which naturally restrict possibilities of development was continually stressed.

Another symposium dealt with world food supply, and was under the chairmanship of Dr. C. E. Kellogg, chief of the United States Soil Survey. As so frequently happens, the speakers from the Old World, notably Prof. George Kuriyan (Madras), stressed the ever-present basic problem of shortage of land, whereas the speakers from the New World were concerned much more with technical problems of development or with economic aspects.

The retiring president, Dr. George Cressey (United States) gave his presidential address under the title "Land for 2·4 Billion Neighbors". The facts adduced leave no doubt that population is increasing far more rapidly than world food supply, and that the long-range solution, given the continued population increase, must be found in sources of food, for example from the sea, not yet regarded as practicable.

A large number of papers were presented at the section meetings which dealt respectively with geomorphology, the teaching of geography, climatology, urban and rural settlement, hydrography, resources, demography, cartography, biogeography, regional geography, historical geography, trade and transportation. In some marked contrast to previous meetings, there was strong support for the section on the teaching of geography, presided over by Prof. C. A. Alagoz (Turkey). Throughout the world there is the growing feeling that international understanding is threatened by the continued ignorance of the citizens of one country concerning the rest of the world, as well as, very often, ignorance of their home country. Instruction in this field is particularly weak throughout the schools and most of the universities of the United States; large gatherings of delegates pressed for a commission to examine the position and to make recommendations. Several of the sections showed an increasing awareness of the need for the application both of their methods of study and their research findings in the solution of some of the great problems of the day.

The same may be said of the afternoon meetings, when the reports of commissions, especially work carried out since the Lisbon Congress of 1949, were under consideration. The commissions reporting included those on industrial ports; medical geography (in the course of which Dr. Jacques May, head of the Medical Research Division of the American Geographical Society, displayed some of the magnificent maps he has in preparation); the international map of the world; regional planning; arid zones; world land use; periglacial morphology; and bibliography of ancient maps.

Normally a commission, limited to six full members, is appointed for one inter-congressional period but may, if its work is incomplete, be reappointed for a further period. No less than thirty-six proposals for commissions had to be considered by the executive, and many which might well have done useful work could not be appointed with any reasonable hope that even minimum financial support would be forthcoming. The final general assembly, having elected officers (see *Nature*, August 30, p. 347), set up eleven commissions to carry on the Union's work until the next Congress, which is planned to take place in Rio de Janeiro during August 1956.

The first four commissions are reappointments, and they are as follows (with the chairman shown in brackets): periglacial morphology (Prof. M. A. Cailleux, France); medical geography (Dr. Jacques May, United States); inventory of world land use (Prof. S. Van Valkenburg, United States); and bibliography of ancient maps (Prof. Roberto Almagia, Italy). A sub-committee on the study of arid zones was constituted as a full commission under the chairmanship of Dr. Peveril Meigs (United States). The new commissions are: coastal sedimentation (Dr. Axel Schou, Denmark); erosion surfaces around the Atlantic (Prof. Francis Ruellan, France); evolution of slopes, including relevant aspect of soil erosion (Prof. Pierre Birot, France, and Prof. Paul Macar, Belgium); geography in schools (Prof. Neville Scarfe, Canada); karst phenomena (Prof. Herbert Lehmann, Germany); and library classification of geographical books and maps (Prof. A. Libault, France).

The commissions are dependent to a considerable extent on the receipt of communications from those who are interested all over the world, and the chairmen may be communicated with through the secretary-treasurer of the Union, Dr. G. H. T. Kimble, American Geographical Society, Broadway at 156th Street, New York 32, N.Y. L. DUDLEY STAMP

INSTRUCTIONAL FILM RESEARCH

A SHORT account of the Pennsylvania State College Instructional Film Research Program was given last year in *Nature*[1], and now a report, written for this research programme, by Charles F. Hoban, jun., and Edward B. van Ormer, has been published*, which reviews the research work done on the instructional film during the thirty-odd years prior to June 1950 at the Pennsylvania State College, and also other work independent of it. In the preparation of this report more than two hundred experimental and survey studies have been examined and more than three hundred are noted in an appendix. These references are predominantly to sources of origin in the United States, where nearly all the research work has been done.

---

* Instructional Film Research 1918–1950. Technical Report No *SDC* 269-7-19. Pp. 200. (Special Devices Center, Port Washington L.I., N.Y.)

Systematic criteria have been applied by the authors in making a selection from the material they have examined. Summaries of all suitable studies, grouped together in relation to various aspects of the instructional film, and the interpretations arising from each group, form the bulk of the report.

General findings previously reached by the Pennsylvania organization have much influenced the theoretical basis for the grouping of these summarized studies. In the present article some of the items in this new report that have not been mentioned before, or stressed, in the Pennsylvania Technical Reports will be indicated.

The film's contribution to comprehension, rather than to rote memory, constitutes one such item. People taught with films are found to be better able to apply their learning than people who have had no film instruction. In tests carried out by P. J. Rulon[2], pupils taught by text-plus-films excelled those taught on a text-only basis by a larger margin on 'eductive' than on 'rote' questions, the ratio being 24·1 to 14 8 per cent. Performance on eductive questions could be predicted more accurately from a knowledge of mental ability and previous achievement than could performance on rote questions. Differences between rote and eductive scores were in the same direction as differences between verbal-test and picture-test scores. From this Rulon concluded that "picture tests measure eduction to a greater extent than do the verbal tests". The contribution of films to comprehension is borne out by the work of P. E. Vernon[3], who conducted an experiment on the value of the film and filmstrip in the instruction of adults. and of J. J. Gibson[4], both of which are also summarized. In Rulon's investigation the superiority of the text-plus-films over the text-only group was found to be greater three and a half months after the films had been shown than it had been immediately afterwards. Several other summarized studies show the contribution of films to a long-term retention of knowledge.

There can be symbolic or mental practice when learning a motor skill from films. Verbal formulations seem greatly to facilitate learning for some individuals. These matters—linked to the larger one of the relationship between language and thought—affect practically the part that can be played by speech in films. The work of M. A. May[5] on the psychology of learning from demonstration films, W. E. Twining[6] on mental practice and physical practice in learning a motor skill, H. A. Ruger[7] on the psychology of efficiency, and several others, is summarized and considered.

Based on the evidence of all the studies, generalization is attempted in the last chapter of the report. According to the authors, people learn more quickly, and retain better what they have learnt, when appropriate films are used than when they are not used. More learning results from a combination of films with other instructional means than by either alone. The learning from films may be of facts, of motor skills, of concepts leading to increased comprehension, and of concepts leading to the formation of attitudes and opinions. Moreover, instructional films stimulate other learning activities. It is possible for a film to be equivalent "even to an excellent instructor in so far as the instructor's function is communicating the facts or demonstrating the procedures presented in the film".

"Films have greatest influence when their content reinforces and extends previous knowledge, attitudes, and motivations of the audience." Three of the ten principles of film-influence again stress the need for specific and confined objectives when designing instructional films, including careful regard for the characteristics of the audience. Four other principles are more distinctively related to the film medium: the influence of films is primarily in their visual presentation; pictorial context is important; the treatment of a film should generally be subjective; and the rate of putting forward new facts and ideas should be properly regulated. In the final principles the importance of introductions, summaries, etc., either built into a film or provided by the teacher, and of the teacher's leadership, are emphasized.

THE ROCKEFELLER FOUNDATION

REPORT FOR 1950–51

A REVIEW of the work of the Rockefeller Foundation for the year 1950 was not published, because any definitive discussion of plans and programmes was impossible while the Foundation was being reorganized to meet the changing conditions of a world in transition. The review by the president, Mr. Chester I. Barnard, now published*, covers the two years 1950 and 1951, during which the Foundation's income was almost 30 million dollars, nearly 17 millions being received in 1951. Grants and appropriations totalled 11,247,964 dollars in 1950 and 21,158,880 dollars in 1951; of this, in 1951, 3,796,270 dollars went to the Division of Medicine and Public Health, which was formed in 1951 by merging the International Health Division and the Medical Sciences Division, these two bodies receiving in 1950 2,326,840 and 1,240,900 dollars, respectively. At the same time, as a further result of a survey of the Foundation's activities, the Natural Sciences Division, which received 2,092,515 dollars in 1950, was reconstituted as the Division of Natural Sciences and Agriculture, to which 3,680,208 dollars went in 1951. A closer co-ordination of all activities of the Foundation was also recommended by the Survey Commission, and Mr. Barnard reaffirms the belief that the broad basis of the Foundation's planning should be human ecology. The Division of Social Sciences received 4,585,895 dollars in 1951, and the Division of Humanities, 1,658,072 dollars; the corresponding figures for 1950 are 2,122,085 and 1,491,250, while a further 5 million dollars in 1951 went to the General Education Board.

Reviewing the work of the Foundation in public health and medicine, Mr. Barnard records that from 1914 to the end of 1951 the Foundation expended nearly 24 million dollars on medical education and research in the medical sciences; nearly 14 millions, more than two decades of work, costing the lives of six scientific workers, went to the isolation and identification of the causal agent of yellow fever and the development of a practical method of culturing the virus for the large-scale production of the vaccine. A definitive history of this work, edited by Dr. G. K. Strode, was published in 1951 under the title "Yellow Fever", and also in 1951 the Nobel Prize in Physiology and Medicine was awarded to Dr. M. Theiler, a virologist on the team which developed the vaccine. The programme of the new Division is now being developed with four objectives: the advancement of professional education; the study of medical care; the investigation and control of specific diseases and deficiencies; and the development of the health sciences.

---

* The Rockefeller Foundation: a Review for 1950 and 1951. By Chester I. Barnard. Pp. 126. (New York: Rockefeller Foundation, 1952).

For the first, it is proposed to make relatively modest grants at strategic points within a faculty to strengthen its teaching, and an exploratory survey is now being made of the status of medical education in South America. The medical care programme will be concentrated on scientific aspects of training and research, especially in the biosociology of disease, in the expectation that, when research has accumulated and systematized the data into a scientific discipline, medical schools will introduce students to the practice of community medicine with an emphasis on 'social diagnosis' comparable to that on physical diagnosis. Under the third objective, special attention is being directed to the study of virus infections transmitted by mosquitoes, ticks, lice and other insects. A survey of the major virus problems of Egypt is being made in co-operation with the United States Naval Medical Research Unit, and a virus research laboratory has been established at Poona in collaboration with the Ministry of Health of the Indian Government. The fourth objective includes a grant to the University of Oregon Medical School for research in constitutional medicine, and grants for studies of child psychology and guidance, medical studies of old age, etc.

In December 1951 the trustees of the Foundation decided that experimental biology would continue to be an active interest in the natural sciences programme but on a reduced scale in the United States, and the greater part of the effort will be devoted to the promotion of scientific agriculture. The Mexican agricultural programme, on which the Foundation has spent more than 1·7 million dollars since its inauguration in 1943, is now operating on an annual appropriation of 320,000 dollars from the Foundation, with additional funds from the Mexican Government, and animal husbandry is being added to the programme in 1952, commencing with chickens and pigs. The Colombia project for the improvement of corn, wheat and other basic food crops, which received 50,000 dollars in 1950 and 135,000 dollars in 1951, has benefited in many ways from the pioneering in Mexico: some of the new varieties of wheat developed for Mexico proved to be remarkably well adapted to Colombia, and under the revised programme for the natural sciences it is proposed to extend similar operating projects in scientific agriculture to other Latin American countries. A further appropriation of 100,000 dollars was made in December 1951 to finance for three years the agricultural aspects of a six-year programme for the agricultural development of the State of Mexico, while a consultant of the Division of Social Sciences is surveying the social problems involved with the view of a co-ordinated 'human ecology' approach to the interrelated problems of food, health, education and social relations.

Apart from these agricultural programmes in Mexico and Colombia, grants made for experimental biology and related fields of science have averaged 2 million dollars in each of the six post-war years and, of this, 1·6 million dollars was distributed in the United States; this amount is to be decreased during the next few years to about 500,000 dollars, while the grants distributed in Europe and in Latin America will be increased to at least 500,000 and 700,000 dollars, respectively, with a further 1·5 millions for the programmes operating in agriculture.

During the period under review the main interest in experimental biology has been biochemistry, and during 1950–51 grants totalling nearly 1·5 million dollars were made for this purpose, including 168,615 dollars to the Polytechnic Institute of Brooklyn for an intensive attack on the problem of protein structure. Grants for enzymology totalled 589,000 dollars, including 35,000 dollars for Prof. H. A. Krebs's work at the University of Sheffield on sugar metabolism. Some 202,000 dollars has been contributed in support of the Conservation Foundation's programme for the study of the conservation of animal and plant life, water sources and productive soils.

In the social sciences the Foundation's programme seeks to assist all the disciplines which can contribute to the development of a science of social behaviour, the application of social science to human problems, the discovery and development of social science talent or the establishment of a firm basis for social philosophy. For research in economics 400,000 dollars were appropriated in 1950 to the National Bureau of Economic Research; 140,000 dollars went in 1951 to Harvard University for Prof. W. Leontief's study of economic structure, and 122,750 dollars went in 1950–51 to the Food Research Institute, Stanford University, partly to complete a five-year study of world operations in food and agriculture during the Second World War. An additional 420,000 dollars were appropriated in 1950 for support over five years of the Russian Institute of the School of International Affairs, Columbia University, and 180,000 dollars to the International Studies Group of the Brookings Institution for research, etc., on American foreign policy. Grants were also made for several studies of problems of ageing, while in December 1951 a capital grant of 1·5 million dollars was made to the Social Science Research Council. Grants totalling 242,500 dollars have been made to the American Law Institute of Philadelphia in furtherance of the preparation of a comprehensive criminal code for recommendation to the State and Federal governments. Altogether, grants for the social sciences totalled more than 2 million dollars in 1950 and more than 4·5 millions in the following year.

A survey of opportunities in the humanities, which commenced in 1950, has led to the selection of three types of humanistic studies for support: first, language, logic and symbolism, representing the Foundation's interest in means of communication of knowledge; intercultural understanding, with the emphasis on the dissemination of knowledge; and humane values. In the first group, 50,000 dollars were appropriated for a detailed analysis and description of the Russian language, under Prof. R. Jakobson at Harvard University, and 69,000 dollars for an integrated study of the theory of language and symbolism at the University of Michigan. In the second, 325,000 dollars were appropriated in 1950 for the studies initiated at Cornell University, with field headquarters at Bangkok, into the effects of technological and economic change on the peoples of South-East Asia, the effects of the United States and the United Nations programmes on the political structures and ideologies in the area, and the status of Chinese and Indian minority groups there. The Institute of Islamic Studies at McGill University, Montreal, has received 214,800 dollars for a five-year period, and grants totalling 194,000 dollars have been made in support of the programme of American studies, launched jointly in 1950 by the University of Tokyo and Stanford University.

The grants, totalling nearly 1·5 million dollars in 1950 and more than 1·6 million dollars in 1951, made through the Division of Humanities, were, Mr. Barnard points out, inspired by the belief that in this field, as in the social sciences, the emphasis is no longer on knowledge but rather on the contribution that may be made to the processes by which our attitudes, beliefs and judgments of value are developed, made more coherent and integrated into a harmonious pattern. If these processes are to be kept healthy in a free society, Mr. Barnard suggests that it is important, first, that the society have creative effort which is really producing new ideas and putting them into understandable forms. Criticism is also essential, to keep creative workers operating on constructive lines; lastly, what Mr. Barnard terms—for want of a more descriptive word —experience is also needed. These are among the reasons which lead the Foundation to foster research and writing in modern history—for example, dramatic writing—and to promote the freedom of the Press. Of the 3,149 applications for aid declined in 1951, 973 were for fellowships, scholarships and travel and training grants, and 618 for support of scientific research projects and teaching programmes.

UNITED STATES PULP AND PAPER INDUSTRIES

In a world where raw materials of all sorts are at a premium, a publication, No. 7 of the Royal School of Forestry, Stockholm, entitled "U.S. Pulp and Paper Industry with Special Reference to its Supply of Raw Material"*, is of particular interest. The consumption in the United States of paper and paperboard prior to the Second World War amounted to about 50 per cent of the total world consumption, and the corresponding figure has now risen to about 70 per cent, owing to the rise in the United States domestic consumption; this latter rose from 15·2 million metric tons in 1940 to 22·5 million metric tons in 1949, the equivalent of an increase from 114 kgm. to 153 kgm. per head of the population. In Sweden, where the consumption per head is probably the largest in Europe, the corresponding consumption for the same year was 80 kgm.

The question is, how are the United States to cover their long-term needs in the way of paper and board, and fundamentally this is a question of raw-material resources. How much can they obtain from their own forests? The balance must be imported. In 1949, 35 per cent of the paper and board consumption was covered by imports in the form of paper, wood pulp or pulp wood. The consumption of pulp wood rose from 14·5 million cubic metres in 1925 to 17·8 million in 1935 and 24·2 million in 1949. In the last-named year the United States imported 4·3 million tons of paper (the bulk of it newsprint), 1·6 million tons of wood pulp and 4·3 million cubic metres of pulp wood. All the pulp wood, the greater bulk of the newsprint, and three-quarters of the wood pulp came from Canada and Newfoundland, and the balance from Scandinavia and Finland.

At the same time the forests of the United States have been yielding a progressively increasing volume of raw material. Pulp wood has increased from 12·7 to 44·7 million cubic metres between 1925 and 1949. This is partly due to the amount coming from new forests in the southern States and Pacific northwest. More intensive valuations of the volume of timber in the coniferous forests are now available, and it is apparent that over-cutting, that is, exceeding the annual increments put on, is taking place in the coniferous forests. In the hardwood forests, for long neglected, the annual increment considerably exceeds the volume felled. It is in this latter type of forest that the United States will have to look in the future for some of their requirements. In how far the annually increasing demands will be met by Canada, Scandinavia and other European countries and so forth is problematical, for Europe requires a far larger amount of these materials than are at present available to her.

PROXIMITY OF GENES CONTROLLING THE FERMENTATION OF SIMILAR CARBOHYDRATES IN SACCHAROMYCES

By Prof. CARL C. LINDEGREN and GERTRUDE LINDEGREN
Biological Research Laboratory, Southern Illinois University, Carbondale, Illinois

Four different genes in *Saccharomyces* controlling the hydrolysis of alpha-glucosidic saccharides are on the same chromosome. The genes *MA*, *MZ* and *MG* controlling the hydrolyses of maltose, melezitose and alpha-methyl glucoside are in one linkage group[1]: (1) *MA* and *MZ* were shown to be linked by frequency of recombination; (2) *MA* and *MG*, which usually recombine freely, were shown to be on the same chromosome by the spontaneous appearance of a crossing-over suppressor in one family. The observations presented here show that *SU* (which controls the fermentation of sucrose and raffinose by producing a beta-fructo furanosidase) is a member of the same linkage group. *Saccharomyces* chromosomes are extraordinarily long genetically, and in most experiments *MA*, *MG* and *SU* recombine independently. Linkage between *MG* and *SU* was revealed by the suppression of crossing-over between them, presumably due to the spontaneous occurrence of an inversion. The pedigree described below overlaps one described earlier[1], and the two cross-over suppressors, one involving *MA* and *MG* and the other involving *MG* and *SU*, may be of common origin.

Experimental. Culture 3608 − − + (non-fermenter of maltose and alpha-methyl glucoside and fermenter of sucrose) is a progeny of a hybrid between 3228 and 3091 (− − + × + − +). The progeny were analysed only for ability to ferment maltose (since the hybrid was homozygous for *mg* and *SU*); in 16 asci, 2 : 2 segregations for *MA*/*ma* were found.

A mating between culture 5519 − − − (non-fermenter of maltose, alpha-methyl glucoside and sucrose) and 7351 + + − (fermenter of maltose and alpha-methyl glucoside and non-fermenter of sucrose) produced the tetrads analysed in family 11. Since family 11 was homozygous for inability to ferment sucrose, only two tetrads were analysed for sucrose fermentation. All eight spores were negative. A high frequency of + to − conversion was encountered in both the *MA* and *MG* genes. The following different types of tetrads were found:

	MA/*ma*	*MG*/*mg*
+ + + −	1	0
+ + − −	29	21
+ − − −	2	6
− − − −	0	1

The concept of gene conversion[3] is applied throughout in analysis of the results.

Family 12 comprised a hybrid between 3608 and 7459; twelve asci showed 2 : 2 segregations of *MG*/*mg*. Only one ascus was characterized with regard to ability to ferment sucrose; all four cultures fermented sucrose despite the fact that one parent was sucrose-positive and the other sucrose-negative. (This situation was frequently encountered while stocks were being built up heterozygous for single pairs of genes controlling specific fermentations[4]. Since both *MZ* and *SU* control the fermentation of sucrose, ratios of this type occur in *MZ SU*/*mz su* hybrids[1].)

The first evidence of linkage between *MG* and *SU* appeared in family 14. The results are summarized in Table 1. In eighteen asci, the combination *mg SU*, characteristic of culture 7554, is accompanied by the alternative arrangement, *MG su*, characteristic of the other parent, 7517: *MG su MG su mg SU mg SU*. In ten other asci two rapid fermenters, one non-fermenter and one late fermenter of sucrose appear: *SU SU su su*^{L}. The analysis of late fermenters of galactose encountered in the Carbondale stocks by Mundkur[5] has shown that they were originally non-fermenters which mutated in the selective medium to fermentative ability. On this interpretation the initial genotype of the tetrads in class 2 would be the same as those in class 1. The close linkage of the two genes found in this family makes the interpretation reasonable and supports the view that late fermenters are originally non-fermenters which afterwards mutate to fermentative ability. The asci in classes 3 and 4 are evidently the same as those in class 1 except for the failure to identify the missing members. Similarly, classes 5 and 6 are identical with class 2 except for the failure to identify the missing members of the tetrad. The anomalous ascus listed in category 7 probably represents crossing-over in the inverted region, with other complications. The two asci in classes 8 and 9 are due to the reduction of tetraploid zygotes; this is indicated by the similar excess of dominants for other factors in the same tetrads.

TABLE 1. TYPES OF ASCI FROM FAMILY 14 SHOWING LINKAGE OF *MG* AND *SU*

Class	Genotype				Frequency
1	*MG su*	*MG su*	*mg SU*	*mg SU*	18
2	*MG su*^{L}	*MG su*	*mg SU*	*mg SU*	10
3	*MG su*	—	*mg SU*	*mg SU*	3
4	*MG su*	*MG su*	*mg SU*	—	2
5	*MG su*	*MG su*^{L}	*mg SU*	—	1
6	*MG su*^{L}	—	*mg SU*	*mg SU*	1
7	*MG SU*	*MG su*^{L}	*mg su*	*mg su*	1
8	*MG SU*	*MG SU*	*MG SU*	*MG SU*	1
9	*MG SU*	*MG SU*	*MG SU*	—	1

No linkage was detected between *MA* and either *MG* or *SU*. Thirty-two of the asci were characterized for capacity to ferment maltose with the following results: + + + −, 2; + + − −, 29; + −^{L} − −, 1. The two + + + − asci were those in classes 8 and 9, confirming the view that they were of polyploid origin.

Family 18 comprised a hybrid between culture 7517 and 8011. It was heterozygous for both *MG* and *SU*. A single ascus analysed from this hybrid showed independent segregation of the genes *MG* and *SU*. By contrast, these markers were almost completely linked in family 14. Since 7517 was used as a parent in producing both families, the linkage of the two markers in family 14 was not transmitted through culture 7517; it must have had its origin from 7554. Culture 7554 has the same combination of factors as culture 3608, supporting the view that the cross-over suppressor was present in family 10.

TABLE 2. TYPES OF ASCI FROM FAMILY 15 SHOWING INDEPENDENT SEGREGATION OF *MG* AND *SU*

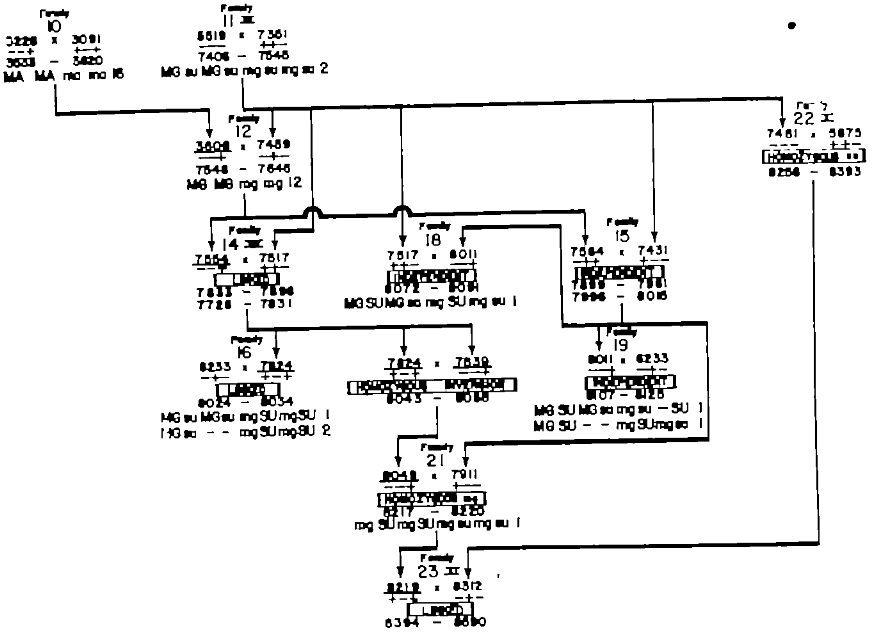
Genotypes				Classes			
				I	II	III	?
MG SU	*MG SU*	*mg su*	*mg su*	3			
MG SU	*MG SU*	*mg su*	*mg su*^{L}	1			
MG su	*MG su*	*mg SU*	*mg SU*		3		
MG su^{L}	*MG su*	*mg SU*	*mg SU*		1		
MG su	*mg*^{L} *su*	*mg SU*	*mg SU*		1		
MG SU	*MG su*	*mg* —	*mg su*			1	
MG SU	*MG su*	*mg SU*	*mg su*^{L}			1	
MG SU	*mg*^{L} *su*	*mg SU*	*mg su*			1	
mg^{L} *SU*	*mg*^{L} *su*	*mg SU*	*mg su*			1	
MG SU	*MG SU*	*mg SU*	*mg SU*				1
MG SU	*MG SU*	*mg*^{L} *SU*	*mg su*				1

Family 15 arose from a hybrid between 7564 and 7431. Culture 7564 is a sibling of 7554 (carrying the cross-over suppressor); 7431 is a sibling of one of the parents of 7554. The segregations of *MG* and *SU* from this family are shown in Table 2; the genes were independently assorted. When the late fermenters are considered as originally negative, the following types of tetrads are found:

	MG/*mg*	*SU*/*su*
+ + − −	12	13
+ − − −	2	0
− − − −	1	0
+ + + +	0	1
+ + + −	0	1

These results indicate that conversion of *MG* to *mg* and of *su* to *SU* was relatively frequent.

The high frequency of recombinations between *MG* and *SU* in family 15 shows clearly that the distance between the genes is greater than 50 morgans. This is confirmed by classifying the asci with regard to segregation of *MG* and *SU* (Class 1, + + + + − − − −; Class II, + − + − − + − +; Class III, + + − − + − − +). The frequency of 4 : 5 : 4 :: 1 : II : III does not differ significantly from 1 : 1 : 4, confirming the absence of linkage. In families 15 and 18, therefore, *MG* and *SU* are independently segregated, while in family 14 they are closely linked.



Pedigree showing the origin of a cross-over suppressor in the alpha-glucosidase chromosome in the Carbondale stock of *Saccharomyces*. Arabic numerals designate the families of interest; the Roman numerals indicate families described previously (ref. 1). The + and – signs under the serial numbers of the parent cultures indicate fermentative ability with regard to maltose, alpha-methyl glucoside and sucrose, in that order

Family 16 arose as a hybrid between 7824 + – + (directly descended from 7554 which carries the cross-over suppressor) and 6233 – + –. Three asci analysed from the hybrid showed that *MG* and *SU* were completely linked in this family.

Family 19 was produced by mating 8011 – – + by 6233 – + – and showed independent segregation of the genes *MG* and *SU* in two tetrads.

These results exclude 6233 as the carrier of the cross-over suppressor and establish 7824 as the carrier, since 6233 by 7824 produced a hybrid in which linkage was complete, while 6233 by 8011 (the latter also carrying the combination *mg SU*) produced tetrads in which independent assortment occurred.

A hybrid was made between 7824 and 7839, both of which carried the inversion. An offspring from this hybrid (8049) was mated to 7911 (descended from family 15 in which independent segregation of *MG* and *SU* occurred). All the *mg SU* offspring of family 21 should carry the inversion. Family 23 was produced by mating an *mg SU* culture from family 21 (8219) with culture 8312, descended from a line in which the inversion did not occur. Thirty-three asci were isolated and analysed (Table 3). No recombinations occurred in the twenty-seven tetrads of class 1. The su^L spores found in tetrads of class 2 suggest the conversion of a dominant gene to a recessive and a later back-mutation. Conversion of *mg* to *MG* occurred in asci of class 3 and *MG* to *mg* in those of class 4. Conversion of *su* to *SU* occurred in the class 5 ascus. Family 23, like family 14, was heterozygous for *MA*/*ma*. No linkage was detected between the *MA* locus and the tightly linked *MG SU* genes. The frequencies of the three classes of *MA MG* tetrads were: type I, 5; type II, 4; type III, 20; this is in complete agreement with the theoretical expectation of 1 : 1 : 4. The following tabulation shows the frequency of conversion of *MG* and *SU*:

	MG/*mg*	*SU*/*su*
+ + + –	2	1
+ + – –	30	30
+ – – –	1	2

The fact that regular segregation of one allele is accompanied by irregularities in the other shows that the two effects arise from different loci although they are completely linked in some families.

TABLE 3. TYPES OF ASCI FROM FAMILY 23 SHOWING LINKAGE OF *MG* AND *SU*

Class	Genotype				Frequency
1	*MG su*	*MG su*	*mg SU*	*mg SU*	27
2	*MG su*	*MG su*	*mg SU*	*mg* su^L	2
3	*MG su*	*MG su*	*mg SU*	*MG SU*	2
4	*MG su*	*mg su*	*mg SU*	mg^L *SU*	1
5	*MG su*	*MG SU*	*mg SU*	*mg SU*	1

It is inferred from these observations that the genes *MG* and *SU* are on the same chromosome; but since neither shows linkage with *MA*, both are more than 50 morgans from the latter.

Discussion. These observations indicate that the genes *MA*, *MZ*, *MG* and *SU* are on the same chromosome. All the substrates except one carry exposed (terminal) alpha-glucosidic linkages: maltose, alpha-methyl glucoside, melezitose, turanose, and sucrose. The exception is raffinose. The genes *MA*, *MZ* and *MG* cannot produce an enzyme capable of action on raffinose. *SU* produces a beta-fructo-furanosidase which hydrolyses both sucrose and raffinose (but not maltose)[5,6].

The high frequency of recombination between these loci does not indicate that the absolute distances between them are great. A single chiasma in each region at each meiosis would produce completely free assortment. No other loci linked to these genes have been found, and it seems difficult to escape the conclusion that their proximity to each other indicates a common origin.

Two other carbohydrases, galactokinase and melibiase, under the control of the genes *GA* and *ME*, are also linked. (The gene *GA* was formerly termed *G*; a two-letter symbolism for all genotypes has been adopted. Three-letter symbols indicate phenotypes.) Their linkage was revealed by recombination[4] and confirmed by the location of another gene for red pigment (AD_1) between them[7]. The fact that one gene controls an enzyme acting on galactose whereas the other acts on a molecule containing galactose suggests that they may have a common origin. *GA* controls the transformation of galactose into a utilizable hexose; *ME* controls the hydrolysis of melibiose into glucose and galactose.

The specially selected non-fermenting clones which were used to build up the Carbondale stock are distinguished from the fermenters by complete inability to ferment or utilize the specified carbohydrate.

These selected recessive stocks are completely without the enzyme necessary to effect utilization of the carbohydrate and are completely incapable of producing it by adaptation. Selection of the nonfermenter stocks has required an extensive, critical survey of a large variety of yeasts. In contrast with these unique, completely negative cultures, cultures are available which are genetically differentiated with regard to utilization of a specific carbohydrate by using it less rapidly than the fully potent culture. There are thus two strikingly different types of genic differentiation of *Saccharomyces* cultures in ability to utilize or ferment carbohydrates: one is unique and involves complete inability either to produce the specific enzyme or to adapt itself to the substrate; the other involves diminution in the ability to ferment the substrate due to a gene-controlled biochemical defect. Two cultures, both carrying the dominant gene controlling the fermentation of galactose, have been differentiated into strong and weak fermenters by such a gene, and segregation of strong versus weak fermentation of galactose has been demonstrated in such a system (Dr. Herschel Roman, personal communication). If defects were present which brought about the absence of specific co-enzymes, a hybrid might show regular segregation for strong versus weak fermentation of maltose and simultaneously show a regular segregation for strong versus weak fermentation of galactose. If more than one enzyme system were involved in the utilization of a single carbohydrate, as has been demonstrated by Leloir and his associates[8] for galactose, more than one gene-pair might be demonstrated controlling strong versus weak fermentation of that carbohydrate. In contrast to this condition, a gene resulting in the complete inability to produce a carbohydrate is inferred to involve the unique gene directly concerned with the formation of the enzyme itself—a gene which might be called the ***enzyme-template*** gene.

On the basis of this discussion, the genes *MA*, *MZ*, *MG* and *SU* (as well as *GA* and *ME*) are identified as enzyme-template genes. Evidence has been presented[6,9] showing that the action of several of these genes is inhibited by the presence of similar substrates, or by the by-products of hydrolysis, suggesting that the gene functions by direct contact of the gene-surface with the substrate, and it is this contact with a topographically specific surface which induces the adaptation. The proximity of the genes *MA*, *MZ*, *MG* and *SU* suggests that they have a common origin and that their number has been increased by unequal crossing-over and mutation of the 'extra' gene[10]. One may assume that *Saccharomyces* originally possessed only a glycolytic system and was incapable of hydrolysing saccharides. That the original novelty with regard to alpha-glucosides comprised either *MA* or *SU* may be inferred from the fact that ability to ferment alpha-methyl glucoside is relatively rare and ability to ferment melezitose is even more unusual. The ability to act on galactose and galactosides is a similar relatively recent novelty. It may be assumed that *GA* was the original novelty, since the ability to act on melibiose is not widespread, and that duplication of the *GA* locus led to transformation of the 'extra' *GA* into the *ME* locus. It has already been suggested[4], on the basis of the mutual exclusion in *Saccharomyces* of ability to ferment maltose and lactose, that the capacity to ferment lactose has its origin in the transformation of the *MA* locus to a locus controlling the capacity for lactose fermentation.

A NEW METHOD FOR ACETYLATING PROTEINS

By DRS. J. BADDILEY, R. A. KEKWICK and E. M. THAIN

Lister Institute of Preventive Medicine, London, S.W.1

RECENT studies by two of us on the chemistry of coenzyme A necessitated the preparation and examination of several acetylthiols[1]. These were required as models to establish a chemical basis for the suggestion that coenzyme A effects acetylations by acetyl transfer at its terminal SH group[2]. The simple acetylthiols were found to be quite effective acetylating agents towards amines in aqueous or alcoholic solution. It appears that acetylthiols in general are capable of acetylating amino compounds, and Wieland and his collaborators[3] have developed a method of peptide synthesis which involves the interaction of such compounds with the amino group of an amino-acid. Alcoholic and phenolic hydroxyl groups are unaffected by these reagents.

The ease with which some of these acetyl derivates reacted towards amines suggested to us their possible use in acetylating amino groups in proteins. The preparation of partially acetylated proteins is of considerable interest in relation to the possible modification of the specific biological activity of enzymes, toxins and hormones, the effect on the immunological specificity of proteins in general and also in connexion with structural investigations. Previously, acetylation was carried out with acetic anhydride, usually in dilute acid solution, or with ketene[4,5]. These reagents are, by their nature, rather unspecific with regard to the group or groups attacked, and the experimental conditions employed leave not a little to be desired, since proteins are often highly sensitive to small changes in their environment and chemical reagents may easily effect deep-seated structural alterations. The acetylation technique described in this article does not suffer from these disadvantages and is, we believe, highly selective.

The substance 2′acetylthioethylacetamide, $CH_3CO.NH.CH_2CH_2S.CO.CH_3$, was chosen for these investigations since it is readily soluble in water, is stable towards dilute acids and alkalis, and acetylates amines quite effectively. Approximate reaction conditions were determined by studying its action on simple amino-acids. An almost quantitative yield of acetylglycine was obtained when the reagent (c. 2 mol.) was added to a 10 per cent solution of the sodium salt of glycine (1 mol.) and the resulting solution kept for 12 hr. at 37°. In a similar experiment with alanine, reaction was only complete after three to four days at 37°.

It was thought that conditions should be chosen to ensure that a reasonable proportion of the amino groups in the substance to be acetylated was in the $—NH_2$ form, as distinct from $—NH_3^+$, in order that the reaction might proceed. Since in proteins the ω-amino group of lysine has a pK value of about 10·5, the earlier experiments were performed in a borate buffer at pH 10.

Human serum albumin isolated by the use of solvents at low temperature[6] was available to us as a protein of established purity (Fig. 1*a*). A 2 per cent solution in borate buffer at pH 10·0, to which had been added 2′acetylthioethylacetamide (to 1·5 per cent) was kept at room temperature during three days, then dialysed exhaustively against phosphate buffer (pH 8, $I = 0·2$) at 2° for examination in the ultra-centrifuge and electrophoresis apparatus. It was expected that the ω-amino groups of the lysine residues and the end α-amino groups in the protein would be acetylated by this treatment.

On electrophoretic examination at pH 8, the product showed two components (Fig. 1*b*), both of which had a mobility considerably greater than that of the untreated protein.

The increase in mobility is consistent with the acetylation of amino groups and consequent increase in net negative charge. In the ultracentrifuge also two components were observed (Fig. 1*b*), a main component sedimenting at approximately the same speed as untreated serum albumin and another component sedimenting more rapidly.

It was considered that the heavy component might have arisen through the reduction of some intramolecular disulphide bonds by the free thiol (2′-mercaptoethylacetamide) derived from the acetylating reagent, the protein —SH groups liberated afterwards reoxidizing to form intermolecular disulphide bonds leading to an increase in molecular weight. Such an explanation was made more probable by the observation that the addition of 2-mercaptoethylamine to a solution of serum albumin under the same conditions resulted in the formation of some faster-sedimenting material and the appearance of two electrophoretic components but without an increased mobility.

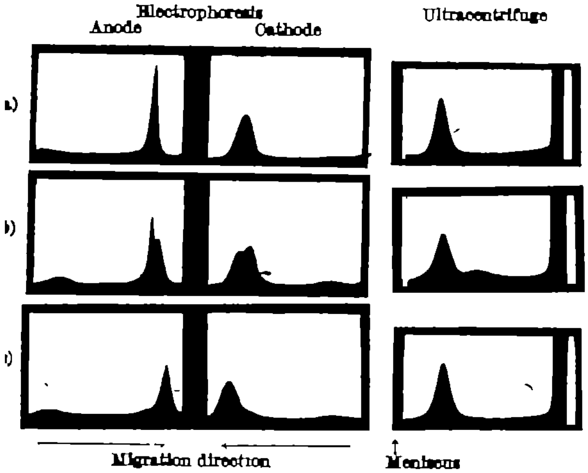

Fig. 1. Electrophoresis and ultracentrifuge diagrams of human serum albumin. (*a*) Untreated; (*b*) Acetylated in deep solution at pH 10; (*c*) acetylated in thin film under oxygen at pH 10. Migration times at 15 m.amp. (*a*) 178 min., (*b*) 98 min., (*c*) 118 min. Ultracentrifuge photographs all after 60 min. at 64,000 r.p.m.

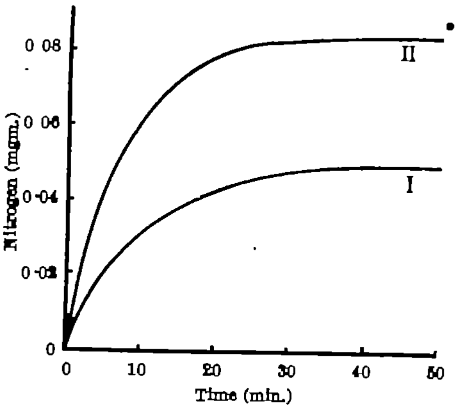

Fig. 2. Van Slyke estimation of amino-nitrogen on 5·25 mgm. samples of acetylated (I) and unacetylated (II) human serum albumin with increasing time of reaction with nitrous acid.

A preparation homogeneous both in the ultracentrifuge and the electrophoresis apparatus (Fig. 1*c*) was obtained by spreading the solution of reactants in a film approximately 2 mm. deep under oxygen to ensure that any thiol produced from the acetylating reagent was rapidly oxidized to innocuous disulphide. The mobility of the single component was 2·1 times that of untreated serum albumin. Furthermore, determination of the free amino groups by the method of Van Slyke indicated that about 34–39 amino groups/mole (70,000) had been acetylated (Fig. 2).

Repetition of this acetylation procedure on the once-treated albumin resulted in no further reduction of amino-nitrogen, as estimated by the Van Slyke method, and the electrophoretic mobilities of the once- and twice-acetylated albumin were identical. This indicates that the single treatment was sufficient to affect the acetylation of all the groups capable of reaction under the experimental conditions.

A further acetylation experiment using the thin-film procedure but at pH 8·5 again gave a product homogeneous in the ultracentrifuge and electrophoresis apparatus. In this instance the electrophoretic mobility of the product at pH 8 was 1·45 times that of untreated albumin, and Van Slyke measurements indicated that some 16–17 amino groups/mole had been acetylated.

It would appear from these results that the number of groups acetylated in the molecule is to some degree dependent on the pH of the reaction mixture, and also, in view of the electrophoretic homogeneity, that all the molecules are acetylated to about the same extent under specified conditions.

The nitrogen liberated from native serum albumin by the Van Slyke procedure was equivalent to 64 amino groups/mole, which is close to the value of 68 given by Brand[7]. After exhaustive acetylation at pH 10 the product still appears to have 25–30 free amino groups/mole. This would appear to imply that, of the fifty-nine lysine residues present in the molecule[7], about half are inaccessible to acetylation under the conditions of reaction employed, assuming that all end α-amino groups, which from the data of Brand[7] amount to 9 groups/mole, are acetylated. A higher reaction pH has not so far been studied, as it was felt that this might of itself cause irreversible changes in the protein.

We are indebted to Dr. Margaret Mackay for the gift of purified human serum albumin and to the Department of Scientific and Industrial Research for a special research grant.

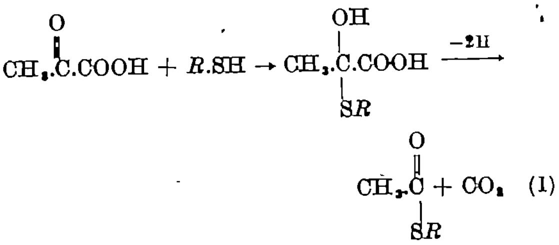
ROLE OF SULPHYDRYL GROUPS IN THE OXIDATION OF PYRUVATE

By Dr. E. C. SLATER

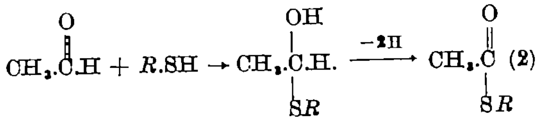
Molteno Institute, University of Cambridge

THE important part played by sulphydryl groups in the oxidation of pyruvate by tissue preparations was established by the work of Peters[1] and Barron[2] and their colleagues. Recently, two essential co-factors required for this oxidation, coenzyme A[3] and α-lipoic acid[4], have been found to contain sulphydryl groups, and Lynen and Reichert[5] have found that this grouping in coenzyme A is concerned in its transacetylation reactions. This prompted Lynen and Reichert to suggest that in the oxidation of pyruvate by pyruvic dehydrogenase, pyruvate or an acetaldehyde derivative formed by the decarboxylation of pyruvate actually combined with the sulphydryl group to form a compound which was oxidatively decarboxylated to acetyl-coenzyme A and carbon dioxide thus (R.SH = coenzyme A):



$$\mathrm{CH_3.}\overset{\overset{\mathrm{O}}{\|}}{\mathrm{C}}\mathrm{.COOH} + R.\mathrm{SH} \rightarrow \mathrm{CH_3.}\underset{\underset{SR}{|}}{\overset{\overset{\mathrm{OH}}{|}}{\mathrm{C}}}\mathrm{.COOH} \xrightarrow{-2\mathrm{H}} \mathrm{CH_3.}\underset{\underset{SR}{|}}{\overset{\overset{\mathrm{O}}{\|}}{\mathrm{C}}} + \mathrm{CO_2} \quad (1)$$

or



$$\mathrm{CH_3.}\overset{\overset{\mathrm{O}}{\|}}{\mathrm{C}}\mathrm{.H} + R.\mathrm{SH} \rightarrow \mathrm{CH_3.}\underset{\underset{SR}{|}}{\overset{\overset{\mathrm{OH}}{|}}{\mathrm{C}}}\mathrm{.H.} \xrightarrow{-2\mathrm{H}} \mathrm{CH_3.}\underset{\underset{SR}{|}}{\overset{\overset{\mathrm{O}}{\|}}{\mathrm{C}}} \quad (2)$$

This is similar to mechanisms proposed for the function of glutathione in the glyoxalase system[6,7] and in the oxidation of glyceraldehyde by cozymase and glyceraldehydephosphate dehydrogenase[7].

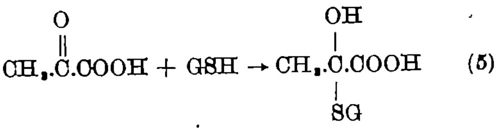
Korkes, Del Campillo, Gunsalus and Ochoa[8] agree with Lynen and Reichert's mechanism and bring forward in its support the experiments of Cavallini[9] on the coupled oxidation of pyruvate in the presence of glutathione (GSH) as a chemical model for the enzymic reaction. Cavallini found that, in the presence of pyruvate, the oxygen uptake exceeded that calculated for the equation:

$$2\,\mathrm{GSH} + \tfrac{1}{2}\,\mathrm{O_2} \rightarrow \mathrm{GSSG} + \mathrm{H_2O}, \qquad (3)$$

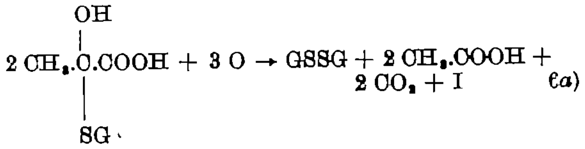
and carbon dioxide was produced in accordance with the oxidative decarboxylation of pyruvate to acetate and carbon dioxide:

$$\mathrm{CH_3.CO.COOH} + \tfrac{1}{2}\,\mathrm{O_2} \rightarrow \mathrm{CH_3.COOH} + \mathrm{CO_2}. \quad (4)$$

He proposed that an intermediate complex was formed which was oxidized thus:

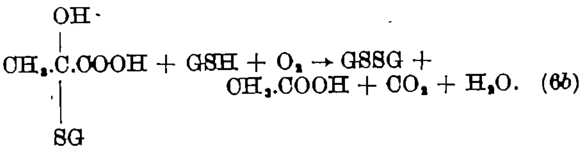


$$\mathrm{CH_3.}\overset{\overset{\mathrm{O}}{\|}}{\mathrm{C}}\mathrm{.COOH} + \mathrm{GSH} \rightarrow \mathrm{CH_3.}\underset{\underset{\mathrm{SG}}{|}}{\overset{\overset{\mathrm{OH}}{|}}{\mathrm{C}}}\mathrm{.COOH} \qquad (5)$$



$$2\,\mathrm{CH_3.}\underset{\underset{\mathrm{SG}}{|}}{\overset{\overset{\mathrm{OH}}{|}}{\mathrm{C}}}\mathrm{.COOH} + 3\,\mathrm{O} \rightarrow \mathrm{GSSG} + 2\,\mathrm{CH_3.COOH} + 2\,\mathrm{CO_2} + \mathrm{I} \qquad (6a)$$

or



$$\mathrm{CH_3.}\underset{\underset{\mathrm{SG}}{|}}{\overset{\overset{\mathrm{OH}}{|}}{\mathrm{C}}}\mathrm{.COOH} + \mathrm{GSH} + \mathrm{O_2} \rightarrow \mathrm{GSSG} + \mathrm{CH_3.COOH} + \mathrm{CO_2} + \mathrm{H_2O}. \qquad (6b)$$

In the light of experiments I have carried out on the copper-catalysed oxidation of 2 : 3 dimercaptopropanol[10], it appeared likely that an alternative mechanism not involving compound-formation between pyruvate and glutathione would explain Cavallini's experiments. The alternative mechanism is described by the following equations:

$$2\,\mathrm{GSH} + \mathrm{O_2} \rightarrow \mathrm{GSSG} + \mathrm{H_2O_2} \qquad (7)$$

$$2\,\mathrm{GSH} + \mathrm{H_2O_2} \rightarrow \mathrm{GSSG} + \mathrm{H_2O} \qquad (8a)$$

$$2\,\mathrm{GSH} + \tfrac{1}{2}\,\mathrm{O_2} \rightarrow \mathrm{GSSG} + \tfrac{1}{2}\,\mathrm{H_2O} \qquad (7 + 8a)$$

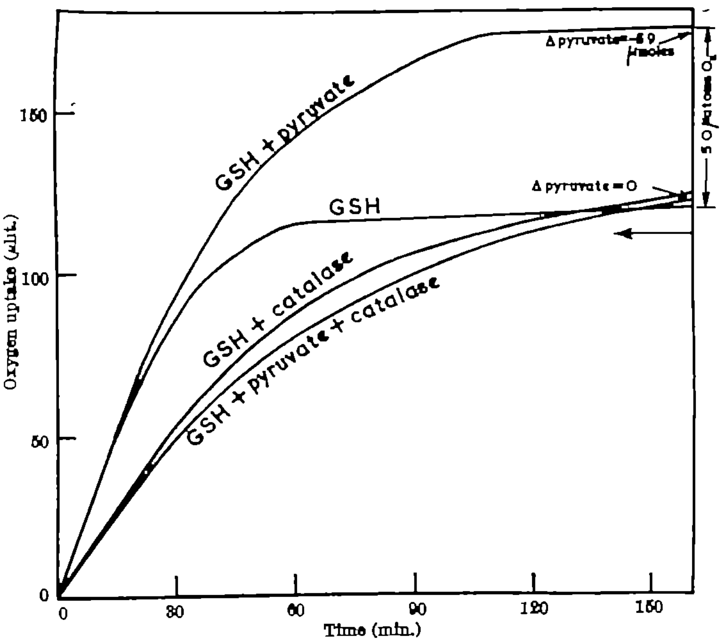
$$\mathrm{CH_3.CO.COOH} + \mathrm{H_2O_2} \rightarrow \mathrm{CH_3.COOH} + \mathrm{CO_2} + \mathrm{H_2O} \qquad (8b)$$

$$2\,\mathrm{GSH} + \mathrm{O_2} + \mathrm{CH_3.CO.COOH} \rightarrow \mathrm{GSSG} + \mathrm{CH_3.COOH} + \mathrm{CO_2} + \mathrm{H_2O}. \qquad (7 + 8b)$$

Hydrogen peroxide is invariably formed in oxidations catalysed by cupric ions. In the absence of pyruvate, this hydrogen peroxide will oxidize additional glutathione, so that there is little accumulation of peroxide at the end of the reaction (cf. Slater, ref. 10, Table 6). In the presence of pyruvate, however, hydrogen peroxide will also oxidize the pyruvate, according to a reaction first shown by Hollemann in 1904[11]. Negelein and Brömel[12] and Keilin and Hartree[13] showed that this non-enzymic reaction took place during the oxidation of D-alanine by D-amino-acid oxidase, both pyruvate and hydrogen peroxide being formed as a result of the action of the enzyme:

$$\text{D-alanine} + \mathrm{O_2} \rightarrow \text{pyruvate} + \mathrm{NH_3} + \mathrm{H_2O_2}. \quad (9)$$

Lipmann[14] showed that, in the oxidation of pyruvate by extracts of *Lactobacillus delbrueckii*, half the pyruvate molecules which were oxidized reacted with enzyme systems in the extract, in which hydrogen atoms eventually reacted with oxygen by means of an autoxidizable flavoprotein, while the remaining half were oxidized non-enzymically by the hydrogen peroxide produced in this autoxidation of the flavine.



Effect of catalase on the coupled oxidation of pyruvate and glutathione

The mechanism proposed in equations (7)–(8) was tested by determining the effect of catalase, which would be expected to have the following effects:

(*a*) Since the hydrogen peroxide produced by reaction (7) would be decomposed by the catalase, thereby liberating oxygen instead of oxidizing glutathione, the initial rate of the net oxygen uptake should be halved by the addition of catalase. In the absence of pyruvate, the final oxygen uptake should not be affected, since either in the presence or absence of catalase, oxygen is reduced to water, not hydrogen peroxide.

(*b*) In the presence of catalase, pyruvate should have no effect on the oxygen uptake, nor should any pyruvate disappear.

The accompanying graph shows the effect of catalase on the coupled oxidation of pyruvate and glutathione. All flasks contained glutathione, cupric chloride and phosphate buffer exactly in the quantities specified by Cavallini[9]; temperature, 38° C. Catalase (0·2 mgm. pure catalase) and/or pyruvate (20 μmoles) was added as indicated. The horizontal arrow shows the oxygen uptake corresponding to equation (3). Δ pyruvate refers to the difference between the contents of reaction vessels after 160 min. and controls incubated without glutathione. The pyruvate was determined spectrophotometrically with lactic dehydrogenase and reduced cozymase[15]. The graph shows that the effect of catalase is in accordance with the mechanism described by equations (7) and (8). In the presence of catalase, there is a slow oxygen uptake after the calculated value is exceeded, but this side-reaction (probably involving oxidized glutathione) does not affect the conclusion, since the curves with and without pyruvate, in the presence of catalase, are very close together.

In the absence of catalase, pyruvate caused the uptake of 5·0 μatoms oxygen in excess of that obtained without pyruvate, and this was accompanied by the disappearance of 5·9 μmoles pyruvate, in good agreement with equation (4). These figures show that, under the conditions of this experiment, approximately half the hydrogen peroxide produced by reaction (7) reacted with glutathione (reaction 8*a*) and half with pyruvate (reaction 8*b*).

The effect of catalase clearly shows that hydrogen peroxide is involved and is strong support for the mechanism proposed, which is, moreover, in accord with well-known reactions. Cavallini's mechanism does not explain the effect of catalase. The mechanism now suggested has the further advantage that it explains Cavallini's earlier experiments[16] in which ascorbic acid was also found to promote the oxidative decarboxylation of pyruvate. The explanation is undoubtedly the same as for the action of glutathione, since hydrogen peroxide is also produced during the copper-catalysed oxidation of ascorbic acid. Indeed, this was the explanation proposed by Cavallini[16] to describe the effect of ascorbic acid.

Since pyruvate is certainly oxidized in animal tissues by the cytochrome system, hydrogen peroxide will not be formed. Thus, there can be little resemblance between the coupled oxidation of pyruvate by glutathione *in vitro* and the oxidation of pyruvate *in vivo*. Cavallini's experiments cannot, then, be considered a satisfactory model of the enzyme. This does not, of course, necessarily mean that the mechanism proposed by Lynen and Reichert and by Korkes *et al.* is incorrect. But it does direct attention to the fact that evidence other than that provided by Cavallini's 'model' experiments must be found. In the case of the glyoxalase reaction, Racker[7] has obtained more direct evidence, since he found that the function of one of the two enzymes in the system is to promote the formation of a compound between methylglyoxal and glutathione. This compound was identified spectrophotometrically and found to be the substrate for the second enzyme of the system. In the present study, spectrophotometric measurements in the ultra-violet region gave no evidence of the formation of a compound between pyruvate and glutathione, under the conditions of Cavallini's experiments.

I wish to thank Prof. D. Keilin for his advice and the Agricultural Research Council for a personal grant.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Secrecy and Industrial Research

In his presidential address to the British Association, on "The Ethical Dilemma of Science", Prof. A. V. Hill referred to the problem of secrecy in relation to the results of industrial research. I believe that the difficulty arises from confusion of technology with science.

These two fields of human endeavour are really quite distinct. Technology is the art of making things. It deals with the methods used for production. In this sense, even animals practise technology, and the evolution of men and the growth of civilization have depended upon the advance of technology. Technology advances by trial and error and by specific inventions. Much of the advance of technology is empirical, and, as Dr. J. B. Conant says, it is by the application of science to technology that the degree of empiricism in technology is reduced. Thus, when we speak of applied science, we mean science applied to technology. In industrial laboratories, the primary purpose of the laboratory is to advance technology, and, in order to do this, scientific work is undertaken so that the scientific results can be applied to advance the technology and reduce its empiricism.

This distinction between the technological work and the scientific work of an industry suggests a policy for the publication of new results. This is that industrial companies should publish their scientific work, but are under no obligation to publish their technological advances.

Scientific advances must be published even when they are applicable to technology because science advances as a whole, and any attempt to withhold the publication of scientific work reacts to the disadvantage of the withholder. Moreover, scientific men will not continue to do satisfactory work unless they can publish that work and feel they are taking part in the advancement of science. The great advance in applied science in the past fifty years is undoubtedly due to the general publication of scientific work done in industry as well as in the universities.

In my opinion, on the other hand, an industrial company is under no obligation to publish information as to its manufacturing technology. Publication is of value only to other firms who use that particular technology. In practice, however, it is impossible to keep technological methods secret for a long time. Often it is necessary to obtain the protection of patents, since otherwise a patent may be obtained by someone else, and a firm that has been using a secret process may find itself unable to use the process. To avoid this difficulty, firms often take out patents even though they desire no monopoly, and thus a great deal of technology is published which would otherwise remain secret.

Technical advances are also often published for purposes of prestige. Sometimes they are published because the applied science cannot be made known without publishing information as to the technology. Holding a technological process secret, therefore, merely delays the publication, and eventually the technology of a few years before it becomes public knowledge.

N-Nitration and *C*-Nitration by the Nitronium Ion

Aromatic *C*-nitration through attack by the nitronium ion was kinetically established by the work of Benford and Ingold[1], and of Hughes, Ingold and Reed[2]. The central point in the evidence was the observation of zeroth-order kinetics in the nitration of suitably reactive aromatic compounds, for example, of toluene, by a constant excess of nitric acid, in organic solvents such as nitromethane or acetic acid. All those aromatic compounds which are sufficiently reactive to take up the nitronium ion as fast as it is formed from nitric acid obey this law, and, for the same medium and temperature, can be observed to become nitrated at an identical rate, which is simply the rate of formation of the nitronium ion.

The zeroth-order form, and the associated absolute reaction-rate, constitute, therefore, a highly diagnostic test for the intervention of the nitronium ion in any reaction in which it is consumed as fast as it is formed. Thus the *N*-nitration of a secondary amine or the *O*-nitration of an alcohol, supposing the amine or the alcohol to be reactive enough, must, if the substituting agent is indeed the nitronium ion, be observable as zeroth-order reactions, having, in fixed conditions, rates identical with each other, and with the rate of nitration, say, of toluene.

We have used this criterion in order to show that the formation of nitroamines from secondary amines, and the formation of alkyl nitrates from alcohols by the action of nitric acid, involve attack by the nitronium ion on the nitrogen or oxygen atom. All kinetic measurements were made by the dilatometric method, controlled by chemical analysis. The course of the conversion of N-methyl : 2 : 4 : 6-trinitroaniline ('methylpicramide') into N-methyl-N : 2 : 4 : 6-tetranitroaniline ('tetryl') by 4 *M* nitric acid in nitromethane at 25° is illustrated in Fig. 1. This *N*-nitration is evidently a zeroth-order reaction. The con-

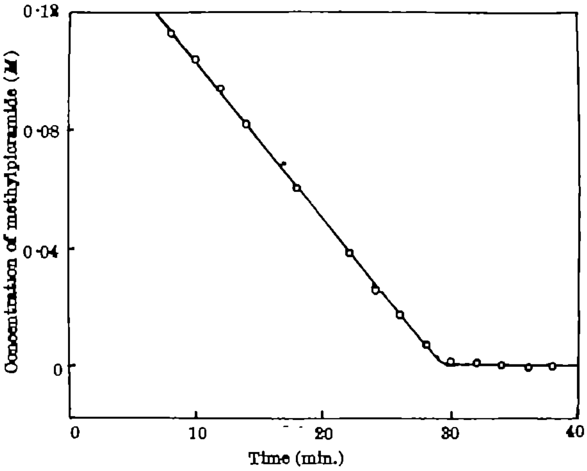

Fig. 1. Nitration of methylpicramide by 3·05 *M* nitric acid in nitromethane at 24·9°

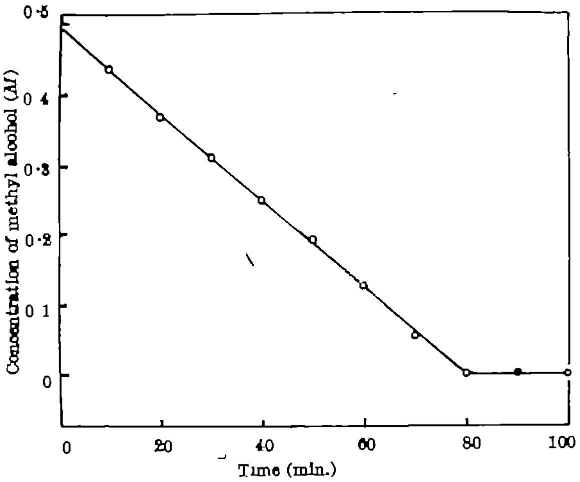

Fig. 2. Nitration of methyl alcohol by 4 0 M nitric acid in nitromethane at 24 9°

version of N-methyl : 2 : 4-dinitroaniline into N-methyl-N : 2 : 4-trinitroaniline proceeds in the same way at the same rate, though the product additionally takes up a *C*-nitro-group in a subsequent much slower reaction of first order, leading to tetryl. The conversion of methyl alcohol into methyl nitrate in similar conditions is likewise a reaction of order zero, as illustrated in Fig. 2. The absolute rate of any of these *N*- and *O*-nitrations is just the same as that of the *C*-nitration of any benzene derivative which uses the zeroth-order form of reaction, as has been shown by direct comparisons under several sets of conditions. Such a comparison with toluene is illustrated in Table 1.

Table 1. COMPARISON OF ZEROTH-ORDER RATES OF *C*-, *N*-, AND *O*-NITRATION BY 4 0 *M* NITRIC ACID IN NITROMETHANE AT 24 9°, WITH $[HNO_2] = 0{\cdot}0076 \pm 0{\cdot}0001\,M$ (UNCHANGED BY NITRATION) THROUGHOUT

Substance nitrated	Initial conc	Rate (mole $l.^{-1}$ sec $^{-1}$)
Toluene	0 099 *M*	10 3 × 10^{-6}
Methylpicramide	0·119 ,,	10 4 ,,
Methyl alcohol	0 491 ,,	10 2 ,,

We know that in *C*-nitration by the nitronium ion, only the more reactive aromatic compounds, such as toluene and benzene, take up the ion as fast as it is produced, and thus exhibit nitration in zeroth-order form. Less reactive aromatic compounds, such as chlorobenzene, take up the nitronium ion less quickly than it is produced, and the absolute rate of nitration is accordingly smaller, while the kinetics now approach first-order form. Similar changes in rate and order are to be expected for *N*- and *O*-nitration, where there is an appropriate suppression of reactivity towards the substituting agent. As illustration, neopentyl alcohol undergoes *O*-nitration by nitric acid in nitromethane much more slowly than does methyl alcohol. Furthermore, the reaction of neopentyl alcohol is approximately of first-order form, and, as is shown in Table 2, the absolute rate is comparable to that of the nitration of chlorobenzene, likewise a reaction of approximately first order, under the same conditions.

Table 2. FIRST-ORDER RATES OF *C*-NITRATION OF CHLOROBENZENE AND OF *O*-NITRATION OF NEOPENTYL ALCOHOL BY 3 77 *M* NITRIC ACID IN NITROMETHANE AT 24 9°

Substance nitrated	Initial conc	Rate constant (sec $^{-1}$)
Chlorobenzene	0·178 *M*	5 53 × 10^{-4}
Neopentyl alcohol	0 176 ,,	4 22 ,,

The *O*-nitration of glycerol and of cellulose is indirectly shown by such model experiments to involve attack on oxygen by the nitronium ion. A direct analysis of the reaction in these cases is complicated by reason of the number of successive steps involved, but progress is being made with the kinetics of nitration of some of the simpler polyhydric alcohols, including glycerol.

We wish to record our appreciation of the interest and help of Prof. C. K. Ingold.

Role of Water in the Structure of Psilomelane, $(Ba,H_2O)_2Mn_5O_{10}$

A SPECIMEN of psilomelane (*BM*.69,160) from Schneeberg, Saxony, was kindly made available for examination by the Department of Mineralogy, British Museum (Natural History). This material forms minute monoclinic crystals with $a = 9{\cdot}56$, $b = 2{\cdot}88$, $c = 13{\cdot}85$ A., $\beta = 92°\ 30'$, probable space group $A\ 2/m$. These values are a refinement of those previously reported by Vaux[1]. The unit cell contains two empirical formula units, $Ba_{0{\cdot}64}(Mn,R)_5O_{10}{\cdot}1{\cdot}36\ H_2O$, giving $d_{calc.} = 4{\cdot}82$, $d_{obs.} = 4{\cdot}71$; the ions R comprise Mn^{2+} and traces of other metals substituted for Mn^{4+}.

The structure, determined by Fourier methods, is based upon double and treble strings of manganese-oxygen octahedra linked in an approximately rectangular grouping by sharing corners to form tunnels parallel to the *b*-axis (Fig. 1). These enclose barium ions and water molecules which are crystallographic-

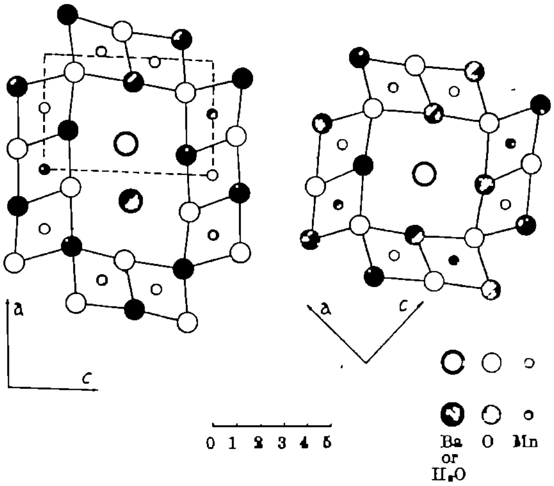

Fig. 1 Fig 2

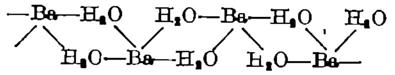
Fig. 1. Structure of psilomelane projected on the *b*-axis. The broken lines enclose an area ½*a* × ½*c*

Fig. 2. Structure of hollandite projected on the *b* (monoclinic)-axis

In each figure, open circles denote atoms at $y = 0$, shaded circles atoms at $y = \frac{1}{2}$

ally indistinguishable. Each of these is situated at the centre of fourteen ions or molecules, the ten approximately equidistant near-neighbours forming the corners of a prism and pyramid. Six are oxygen atoms, the remainder equivalent (Ba,H_2O) groups. The latter each has an identical fourteen-fold grouping, so that a double row of barium ions and water molecules is situated in a tunnel.

The ratio $Ba : H_2O$ is very nearly equal to 1 : 2. In order to prohibit two barium ions from being near-neighbours, the most logical stacking sequence in the double rows is :



There is no diffraction evidence to support this view, despite a sufficient difference between the scattering-power of two molecules of water and of one barium ion to demonstrate such a grouping if it existed. Nevertheless, this arrangement is the only one which is feasible on electrostatic grounds, and the double rows of (Ba,H_2O) units, therefore, are probably disordered with respect to one another.

The dehydration of psilomelane, which resembles that of the zeolites, is accompanied by a phase transition to hollandite (Fig. 2) when most of the water is removed. It is evident that too many vacant sites are created in the double row for structural stability, and the collapse to hollandite is effected by the rearrangement of treble strings of octahedra into double strings, and the double row of barium ions into a single row.

Despite the smaller unit cell of hollandite, there are insufficient barium ions to fill all the sites in a single row. The formula of hollandite, deduced from that of the psilomelane used in this investigation, is $Ba_{1\cdot01}(Mn,R)_8O_{16}$, in good agreement with that previously proposed by Byström and Byström[2], $Ba_{(2-x)}Mn_8O_{16}$, where x is approximately equal to one. It has been suggested[3] that discrete water molecules may be present in hollandite as occupants of vacant sites of otherwise perfect sub-rows :

—vac.—Ba—vac.—Ba—vac., etc.

This speculation receives support from the proposed structure of psilomelane.

A more detailed account will shortly be presented for publication elsewhere.

Electronic Orbitals, Shapes and Spectra of Polyatomic Molecules

Our ideas and knowledge of the shapes of polyatomic molecules are largely confined to the ground electronic states. Comparatively little progress has been made in knowledge of the symmetries of electronically excited states. Not infrequently it has been tacitly, but unjustifiably, assumed that the excited state of a molecule has the same symmetry as the ground-state. Bound up with this, spectroscopists, having made a vibrational analysis of a spectrum, have often been content to leave it at that ; they have not tried to answer the question as to why particular vibrations occur. There have been exceptions, of course—the occurrence of the breathing vibration of benzene on electronic excitation near 2600 A. has been, for example, very reasonably attributed to an expansion of the benzene ring in the upper state—but, especially with non-totally symmetrical vibrations, it is usually true that no explanation has been offered for the occurrence of particular modes of vibration. Why, for example, do e_g^+ vibrations occur in the near ultra-violet spectrum of benzene ? That these enable an otherwise forbidden transition to become allowed is, of course, no explanation of why they occur.

For some time I have been interested in this problem of the shapes of electronically excited molecules. My procedure has been first to decide the molecular orbitals possible for two particular shapes of a particular molecule ; then to decide which orbital of the one symmetry class must transform to a particular orbital of the other symmetry class when some parameter is varied from its value for one shape to its value for the other ; and finally to decide whether a particular orbital becomes more or less tightly bound as that parameter is varied. The resulting correlation diagram is of great value, for it implies what will be the most stable shape for any electron configuration (including the ground-state) ; and hence what vibrations are likely to be aroused in a particular electronic transition and whether the maximum intensity will be close to or far from the origin of the system ; what will be the formulation of the longest wave-length transitions and hence whether these transitions will be allowed or forbidden ; and, if the former, how they will be polarized. This procedure has been applied first to triatomic molecules (AH_2, AB_2, BAC, HAB molecules) ; then to tetratomic molecules (AH_3, AB_3, H_2AB, B_2AC molecules) ; then to the methyl halide molecules ; then to ethylene and more complicated molecules. A brief verbal account of the work was given to the International Conference of Spectroscopists at Basle in June 1951 [1], and a full account is now being submitted for publication elsewhere. In this communication, I wish to summarize some of the outstanding results. Some of them have been obtained before, but not as part of a comprehensive treatment.

(1) AH_2 molecules containing 4 valency electrons should be linear in their ground-states. Those containing 5, 6, 7 or 8 electrons should be bent in their ground-states. The first excited states of 4-electron AH_2 molecules should be bent.

(2) Non-hydride triatomic molecules containing 16 valency electrons should be linear in their ground-states. 17, 18, 19, 20-electron molecules should be bent, the apex angle decreasing with increase in number of electrons. The first excited states of 16-electron molecules should be bent.

(3) HAB molecules containing 10 valency electrons should be linear in their ground-states. Molecules with more than 10 electrons should be bent in their ground-states. The first excited state of HCN should be bent. The first excited state of C_2H_2, which is *iso*-electronic with HCN, should be non-linear.

(4) AH_3 molecules containing 6 valency electrons should be planar in their ground-states, pyramidal in their first excited states. AH_3 molecules containing more than 6 valency electrons should be pyramidal in their ground-states.

(5) AB_2 or B_2AC molecules containing 24 valency electrons should be planar in their ground-states, but pyramidal (if stable) in their first excited states. 25-, 26- and 28-electron molecules should be pyramidal in their ground-states, the BAB or BAC angle decreasing as the number of electrons increases.

(6) If X is the centre of the mid-point of the H—H line, the first excited state of the HCHO molecule should have the XCO line bent both in the molecular plane and out of that plane. The distortion is insufficient for the classification of the levels according to the C_{2v} symmetry operations to lose its importance, but sufficient to cause the $\nu_5 b_2$ and $\nu_6 b_1$ vibrations to appear in the spectrum. It has been possible to give a complete vibrational analysis of the fluorescence bands and make plausible assignments of the long-wave-length absorption bands.

(7) The first excited state of the C_2H_4 molecule should have · (a) one CH_2 group twisted through 90° relative to the other, (b) a pyramidal arrangement of the bonds about each carbon atom. The first excited state of a molecule containing n electrons should have the same symmetry as the ground-state of the similar molecule containing $n + 1$ or $n + 2$ electrons. It therefore becomes possible to confirm these statements concerning the first excited state of C_2H_4 by comparison with what is known of the ground-state symmetry of N_2H_4.

(8) The first Rydberg state of the CH_3I molecule should have: (a) a considerably decreased HCH angle, (b) the iodine atom off the trigonal axis of the CH_3 group. (a) causes the totally symmetrical CH_3 deformation vibration to appear in the spectrum; (b) causes the $\nu_6 e$ vibration to appear. (a) is particularly striking since the excitation is of an iodine electron which, superficially, one might have expected not to affect the CH_3 group.

(9) The C_6H_6 molecule should be distorted in its first excited states both in the molecular plane and out of that plane. The distortion is insufficient for the classification of the levels according to the D_{6h} symmetry operations to lose its importance, but sufficient to cause the appearance of a wide variety of in-plane and out-of-plane deformation vibrations.

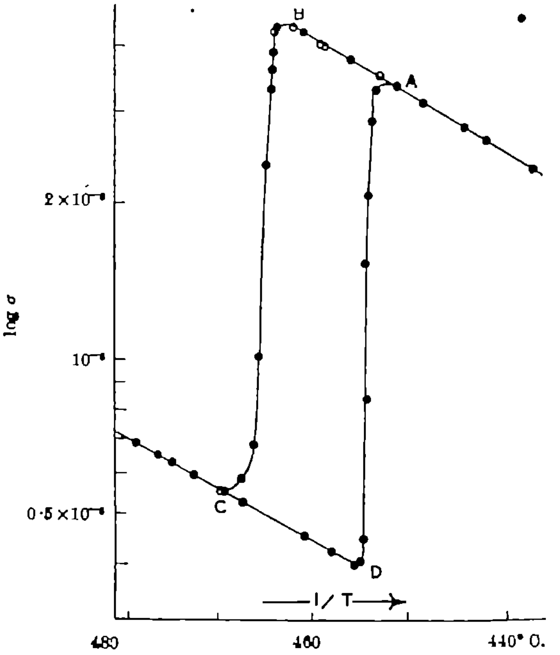
Electrical Conductivity of Cæsium Chloride near the Thermal Transition

AT normal temperatures, cæsium chloride is stable in a body-centred cubic lattice, and at higher temperatures in a simple face-centred lattice of the sodium chloride type. When single crystals were heated, it was found, using X-ray techniques, that a sharp transition occurred from one form to the other at 469°. Indications were, however, obtained that certain intensities of X-ray reflexions faded exceptionally rapidly on approaching the transition point[1]. This suggested that lattice defects of some kind might be increasing rapidly in number around the transition temperature. If these defects are of the type associated with ionic conductivity in crystals, a marked increase of electrical conductivity should be observed on passing through the transition point.



●—●—, Descending temperature, O—O—, ascending temperature

Measurements have now been made of the conductivity of cæsium chloride crystals in the form of a polycrystalline mass chilled from the melt between two platinum electrodes. Instead of a rise, a steep drop in conductivity is observed on passing through the transition point. Marked hysteresis is observed around the transition; but above and below it the results are quite reproducible (see graph). The temperature coefficient of conductivity is found to be very approximately the same above and below the transition point, so that the steep drop in conductivity on passing to the high-temperature form must be due to the influence of crystal structure on the temperature-independent parameter σ_0 in the semi-empirical expression for the conductivity, $\log \sigma = \sigma_0 - E/kT$. It seems clear that if there is any pre-transition break-up of the lattice, it cannot be of the kind associated with the defects responsible for ionic conductivity. A similar drop in conductivity has been reported for thermal transitions[2] in mercuric iodide (137° C.) and potassium nitrate (128° C.).

Paper Electromigration of Flavonoids and Sugars using a High Constant-voltage Current

ALL but a few[1] of the numerous reports in the past few years on the application of electromigration or electrophoresis on paper have used a comparatively low voltage. Recently, however, a method of paper electromigration which uses a high constant-voltage current has been developed in these laboratories and appears to offer a more convenient and rapid procedure than ordinary paper chromatography.

The apparatus for delivery of a current of constant voltage from 100 V. to 1,000 V. is made by modification of that used by Heigl *et al.* as the constant-voltage generator for the photomultiplier of their Raman-spectrum apparatus[2]. In principle, the apparatus for determining migration distance is similar to that of Durrum, with, however, only one cabinet which contains the supporting glass rod for the filter paper and two vessels for electrolyte solutions into which carbon electrodes are dipped.

In use, a filter-paper strip 0·5–2 cm. wide and 40 cm. long is hung from the glass rod with both ends immersed in electrolyte. After applying the substance on the apex, current is passed for 2–4 hr. and the spots revealed by ultra-violet light (3650 A.) or spray reagents. The following examples illustrate the method.

(1) *Flavonoids*. The sample is dissolved in formamide, spotted on the centre of the strip and dried. To detect the spots after migration, the paper is immersed in a 5 per cent ethereal solution of lithium aluminium hydride, dried quickly by hot air, and sprayed with water or dilute hydrochloric acid. The spots appear reddish-yellow or dark green, possibly through the formation of lithium or aluminium complex salts.

In Table 1, where borax is used as the electrolyte, it is interesting to note the relation between the number of adjacent *cis*-hydroxyl groups of the sugar, or the number of vicinal dihydroxy groups of the aglycone, and the migration distance.

Table 1

Flavonoid	No. of adjacent *cis*-OH of sugar	No. of vicinal dihydroxy groups of aglycone	Migration distance to cathode (4 hr.) in mm
Myricitrin	1	1	30
Rutin	1	1	25
Quercetin	0	1	16
Myricetin	0	1	10
Luteolin-7-glucoside	0	1	3
Naringin	0	1	3
Hesperidin	0	0	3
Acacetin	0	0	3
Morin	0	0	2
Robinin	0	0	2

Current. 500 V., 1·5 m amp./cm. width. Paper Toyo filter paper No. 50. Electrolyte: 2 per cent borax solution.

(2) *Sugars*. By application of high-voltage electromigration, all types of sugars may be separated, borax solution proving the best electrolyte (see Table 2).

Table 2

Sugar	Migration distance (4 hr.) in mm.		
	I	II	III
Fructose	+ 67	– 18	– 34
Glucose	+ 56	– 28	– 47

Colorimetric Determination of Formaldehyde under Mild Conditions

IN the course of work on the neutralization of formaldehyde in living bacterial cultures, it was found that the Hantzsch reaction between acetylacetone, ammonia and formaldehyde proceeded so readily at pH 6 that it afforded a good method of estimating microgram amounts of the latter. The yellow colour due to the formation of diacetyl-dihydro-lutidine is fully developed in two hours at room temperature, the molecular extinction being 8,000 at 412 mμ. The reaction will be fully described elsewhere; but a suitable reagent is known to be $M/20$ acetylacetone and $M/30$ acetic acid in molar aqueous ammonium acetate. The only unexpected interfering substance found was sulphite.

Detailed accounts of this work will be submitted elsewhere.

A Substance in Animal Tissues which stimulates Ketone-Body Excretion

IT has been known for many years that the glycosuria of clinical diabetes can be prevented by feeding a very high fat diet. Petren[1] showed that if the fat content of the diet was sufficiently great and if the protein content was restricted, the ketosis of diabetes could likewise be abolished. This observation was confirmed by Marks and Young[2] in dogs rendered permanently diabetic by the injection of anterior pituitary extract. They showed not only that a diet consisting entirely of beef suet produced a remission of diabetic glycosuria and ketonuria, but also that the addition of raw horse meat to such a diet caused an exacerbation of ketone body excretion. They were able to extract the factor in the horse meat responsible for the ketonuria and demonstrated that this material was not present in significant quantities in casein. Burn, Lewis and Kelsey[3] showed that alloxan-diabetic rats could be maintained without glycosuria on a high fat diet. Bornstein and Nelson[4] extended these observations and noted that alloxan-diabetic rats exhibiting ketonuria on moderately high fat diets ceased to excrete ketone bodies when the fat content of the diet exceeded 70 per cent. Lazaris and Brzezhinskaya[5] demonstrated that the critical factor in the ketosis of diabetic rats on a high fat diet was the presence or absence of animal protein in the diet. When 'albumenous' material was added to the diet, ketosis ensued, whereas other dietary constituents had no ketogenic effect.

The present study has been devoted to the isolation and characterization of the substance in meat which produces ketonuria when administered to an animal on a high fat diet. Normal black-and-white male rats of the inbred laboratory strain and weighing approximately 180 gm. were placed on a diet consisting of margarine 70 per cent, protein 6 per cent, salt mixture 5 per cent and water 19 per cent, for a period long enough to produce a loss in weight equivalent to 35–40 per cent of the initial body-weight. The diet was then reinforced with all the known B-vitamins. The precipitous fall in weight produced by the unsupplemented diet was arrested by the addition of B-vitamins and, thereafter, the animals maintained their weight or grew slightly. When the protein of the diet consisted of vitamin-free casein, the animals showed little or no ketonuria after 10–14 days on B-vitamins, while animals receiving a washed heat-coagulated dried horse-meat preparation showed a moderate to severe ketonuria (see accompanying table).

Diet	No. of determinations	Total ketone-body excretion* as mgm. acetone/24 hr.
70 per cent margarine + casein	21	0·45 ± 0·22
70 per cent margarine + horse meat	14	11·04 ± 5·25

* Determined by the method of Greenberg and Lester (ref. 6)

The stimulating effect of tissue extracts on ketone-body excretion can be tested in rats fed on the high fat diet containing casein as the protein constituent. Using this test as a rough guide, a fractionation of horse muscle has shown that the ketone-body stimulating substance present in horse muscle resides in the lipid portion and can be recovered chiefly from the mono-amino phosphatide fraction.

Fractional precipitation of *n*-butanol extracts of lyophilized horse muscle has yielded a preparation the properties of which are constant. The preparation is white, crystalline and possesses a sharp melting point (53°) which does not change on repeated re-melting. A chloroform solution of the preparation is optically inactive, and the material is not subject to discoloration on prolonged exposure to air. Sodium fusion gives no evidence of nitrogen, phosphorus, sulphur or halogen, and an emission spectrum fails to demonstrate any significant metallic component. The material reacts with 2 : 4-dinitrophenylhydrazine and can be condensed with benzaldehyde to form a benzylidene derivative. It does not possess the reactions of an aldehyde and is therefore a ketone. The infra-red absorption spectrum (kindly prepared and interpreted by Dr. R. N. Haszeldine, of the Department of Chemistry) confirms chemical evidence suggesting the absence of other reactive groupings, and an absorption band at 5·73 μ supports the probability of a ketone structure. Elemental analysis (by Weiler and Strauss), C : 76·5, H : 12·8, O (by difference) : 10·6 per cent.

Lipid residues obtained from *n*-butanol extraction of calf intestinal mucosa kindly provided by Dr. R. K. Morton were subjected to a purification similar to that above. The material obtained had a melting point of 53°, and a mixed-melting point determination with material obtained from horse muscle showed no depression. The infra-red absorption spectrum of this material from calf intestine showed negligible differences when compared with that obtained from the horse-muscle ketone.

When the ketonic substance from muscle is fed or administered by stomach tube to rats receiving the casein-containing high fat diet, an increase in ketonuria lasting some days is consistently observed. It has not yet been possible to produce a response as great as that observed in animals receiving horse meat in place of casein; but methods of administration and dosage have not yet been completely explored.

It seems likely, therefore, that most of, if not all, the urinary ketone bodies excreted by rats receiving a high fat diet supplemented with meat protein result from the activity of a non-protein component of the meat. The earlier observations were made exclusively in diabetic patients or in animals rendered diabetic by experimental procedures. The present study, in which both alloxan-diabetic and normal rats have been used, indicates that this metabolic factor exerts its effect in normal as well as diabetic animals. The chemical nature of this substance and the means whereby it alters the metabolic pattern are under active investigation in this laboratory.

One of us (H. B. S.) would like to express his gratitude to the Merck Fellowship Board of the National Research Council of Canada, without the generous support of which this work would not have been possible.

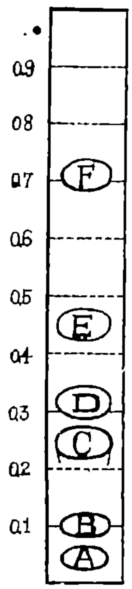
Relation of 3-Hydroxykynurenine to the Ehrlich Diazo Reaction of Urine in Severe Tuberculosis

IT is well known that the urines of cases of severe tuberculosis often show the diazo reaction and the urochromogen test of Weiss. Recently, we have been trying to separate and to identify the substance responsible for these reactions. The results obtained are as follows. 700 ml. of urine obtained from a severe case of tuberculosis, which gave a strong diazo reaction and the urochromogen test of Weiss, was, after being saturated with ammonium sulphate and filtered, shaken vigorously with 140 ml. of 90 per cent phenol. After standing, the separated phenol layer (115 ml.) was shaken with a mixture of 115 ml. of ether with 55 ml. of water. After standing again, we took the separated water layer, which showed a brown colour, and washed it repeatedly with ether until the ether washing showed no more colour. The water extract was concentrated *in vacuo* to 15 ml., in which the greater part of the substance in question was collected. Further purification was performed by chromatographing on filter paper No. 50 of the Tōyō Filter Paper Company, Tokyo, using a system of *n*-butanol, acetic acid and water (4 : 1 : 5) as the developer, ascending method. The concentrate was developed as spots on filter paper strips or wider papers (40 cm. × 40 cm.) for 20 hr. Under ultra-violet illumination, six strongly fluorescent spots appeared (*A*, *B*, *C*, *D*, *E*, *F* in diagram).



Approximate R_F values of fluorescent spots obtained from urine of the severe tuberculous patient on paper chromatography in butanol–acetic acid

Spot *C* represents 3-hydroxykynurenine; it gives an intense fluorescence, the ninhydrin reaction, a strong diazo reaction, and reduces permanganate solution. With the aldehyde reagent (a solution of *p*-dimethylaminobenzaldehyde in hydrochloric acid) it shows a red colour. Synthetic 3-hydroxykynurenine has the same R_F value (0·25) and the same colour tests with the reagents mentioned above.

In addition, the band showing this R_F on the developed filter paper was cut with scissors and extracted with water and the solution examined spectroscopically. Its ultra-violet absorption spectra ($\lambda_{1\,max.} = 270$, $\lambda_{2\,max} = 370$ mμ) were identical in type with those of 3-hydroxykynurenine.

Spot *D* was identified as due to kynurenine by comparison of R_F by paper chromatography with the synthetic compound, with the ninhydrin reaction and the Otani–Honda test. It shows no Ehrlich diazo reaction or the urochromogen reaction of Weiss. Spot *E* is a mixture of kynurenic and xanthurenic acids, because the spot shows the same R_F value on the paper chromatograph as that of these two acids (in our technique these two acids cannot be separated from each other) and gives an intense green colour with ferric chloride solution, Kretschy's colour test, an orange colour with Ehrlich's aldehyde reagent and the urochromogen reaction, but does not show the ninhydrin reaction.

As in the case of B_6-deficient rats[1] fed supplementary tryptophane, it seems probable that the urine of our tuberculous patient might contain, in addition to kynurenine, 3-hydroxykynurenine, kynurenic and xanthurenic acids and conjugation products of these substances.

In fact, the presence of N^{α}-acetyl-3-hydroxykynurenine and a conjugated product of xanthurenic acid might be postulated with high probability, though their amount seems to be small. Spot *F* corresponds to the former because its R_F resembles that of N^{α}-acetyl-3-hydroxykynurenine, which was indicated in the literature[1], and gives the diazo reaction without giving the ninhydrin reaction. Spot *B* corresponds to the conjugate of xanthurenic acid[1], and shows a fainter diazo reaction.

Spot *A* coincides with 3-hydroxykynurenine *o*-glycuronide described by Dalgliesh *et al.*[1] from its ultra-violet absorption spectra ($\lambda_{max.} = 269$ mμ), the R_F on the paper chromatograph, by giving the ninhydrin test but no Ehrlich diazo reaction.

In conclusion, we can say that the major substance which is responsible for the diazo reaction of Ehrlich and the urochromogen test of Weiss is 3-hydroxykynurenine, an intermediate of tryptophane metabolism. Here it must be added that some time since, Dr. S. Oka in this laboratory was able to separate a 3-hydroxyanthranilic acid-like substance by paper chromatography (R_F 0·84, the same as that of pure 3-hydroxyanthranilic acid; positive diazo reaction) from the fraction which was obtained by precipitation with mercuric sulphate from the alcoholic extract of the diazo urine.

We are much indebted to Mr. S. Taga for technical assistance. We thank Prof. T. Sakan for gifts of synthetic 3-hydroxykynurenine and kynurenine, and Prof. Yashiro Kotake and Prof. Yahito Kotake for gifts of kynurenic and xanthurenic acids. To Dr. C. E. Dalgliesh *et al.* we are also indebted for pointing out the identification of the various spots described by them in *Nature*[1] and the relevant ultraviolet spectra.

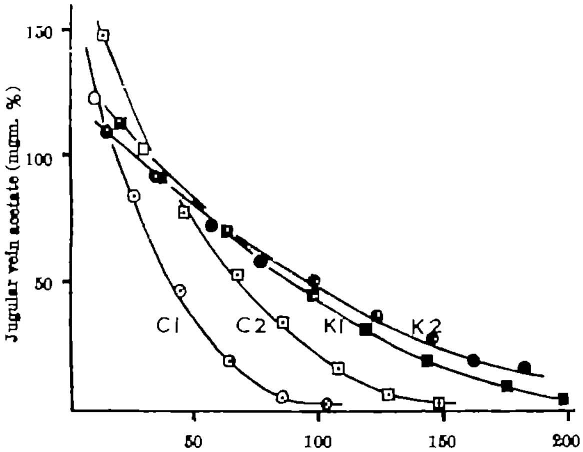
Acetate Metabolism in Ovine Ketosis

DURING the course of an investigation into ketosis in sheep, it was found that ketonæmia in the sheep is accompanied by a marked decrease in the rate at which injected acetate is metabolized.

The technique used was, in effect, an acetate-tolerance test: ewes for the control series were deprived of food for twenty hours before experiment, and then a standard dose of sodium acetate, equivalent to 500 mgm. acetic acid per kgm. body-weight, was injected into the jugular vein. The disappearance of acetate from the circulation and the appearance of ketone bodies were followed by taking samples of venous blood at intervals. Less than 5 per cent of the injected dose appeared in the urine in normal animals. Results have been obtained for sixteen normal ewes at different stages of pregnancy from 60 days to term, and for nine ewes, within two weeks of parturition, showing varying degrees of ketonæmia. The level of ketone bodies in the ketonæmic ewes varied from 9·3 mgm. to 25·5 mgm. per cent (measured and expressed as acetone per 100 ml. whole blood). The disappearance of acetate from the blood was slower in all the ketonæmic ewes than in the normal ewes. Four of the results have been plotted in the accompanying graph. The two curves. *C*1 and *C*2, show the fastest and slowest rates at which the injected acetate was metabolized in the group of sixteen control ewes. The other two curves, *K*1 and *K*2, were obtained from two cases of ketosis in ewes in which the level of ketone bodies were 15·4 mgm. and 17·5 mgm. per cent respectively.

In the ketonæmic animals studied, it was found that the higher the resting-level of ketone bodies. the more marked was the decrease in the rate of disappearance of acetate.



Disappearance of injected acetate. *C*1 and *C*2 give extreme findings in sixteen normal sheep during pregnancy. *K*1 and *K*2 are from two animals with ketosis in late pregnancy

Acetate has frequently been shown to be a precursor of ketone bodies. The injection into sheep of large amounts of acetate results in a small rise in the level of circulating ketone bodies[1]: in the control ewes of this series this was very reproducible both as regards magnitude and duration. In the ketonæmic animals, the acetate injection produced a different response, in that the rise in circulating ketone bodies was both delayed and smaller in amount to an extent which varied with the degree to which the metabolism of acetate was impaired. In these sheep the greater the degree of ketonæmia the less was the apparent conversion of exogenous acetate to ketone bodies.

There is a possible relationship between this derangement and the decreased rate of production of carbon dioxide from isotopically labelled acetate demonstrated *in vivo* in the fasting rat by Coniglio, Anderson and Robinson[2]. The significance of these findings in the sheep, in which the metabolism of absorbed acetate provides an important part of the energy requirements, and their possible relationship to the problem of ketosis, are the subjects of further investigation.

Relation between Total and Exchangeable Sodium in the Body

EARLY workers, who studied the fate of sodium-24 administered to animals, showed that the isotope exchanged with the sodium of the tissues[1]. They assumed that all the body sodium participated in this exchange. That this assumption is incorrect was suggested by recent results obtained with dogs[2] and humans[3-5], in which 20–35 per cent of the body sodium was estimated to be non-exchangeable with plasma sodium-24.

In order to study directly the relationship between total sodium and exchangeable sodium, sodium-24 was injected intravenously into six adult, well-nourished rabbits. Blood samples were taken periodically and analysed for their radioactivity and sodium content. After varying times (6–96 hr.), the rabbits were killed and small samples of tissues were taken. The bodies were then minced. The tissue samples and portions of the well-mixed minces were dissolved in nitric acid and their radioactivity and sodium content determined[5].

The exchangeable sodium, obtained from analysis of blood samples, was 48 ± 0·75 (s.e.) m.mol. sodium/kgm. body-weight, the value given by analysis of the minces being 46 ± 1·13 m.mol. sodium/kgm. body-weight. These figures are not significantly different, and show that the usual clinical method of measuring exchangeable sodium, as the ratio of the total radioactivity in the patient to the specific activity of the plasma, gives valid results. The total sodium of the rabbits was 62 ± 1·5 m.mol. sodium/kgm. body-weight, that is, the exchangeable sodium was 69 ± 1·7 per cent of the total sodium. The non-exchangeable sodium of the rabbits therefore was 16 ± 1·9 m.mol./kgm. body-weight.

Studies of the exchange of plasma sodium-24 with the sodium of bone in dogs[2] and humans[3,4] have shown that 55–70 per cent of the bone sodium is non-exchangeable. In rabbits[6] this figure is 61–68 per cent. Since the average sodium content of the rabbit bones was 270 m.mol./kgm. bone, the non-exchangeable sodium of bone was about 170 m.mol./kgm. bone; and, as direct measurements exclude the presence of any other major store of non-exchangeable sodium in the rabbit, this means that the bones constituted approximately 10 per cent of the total body-weight, a figure in good agreement with direct determinations[7].

These experiments therefore show that virtually all the non-exchangeable sodium of the rabbit is located in bone and is about 28 per cent of the total body-sodium.

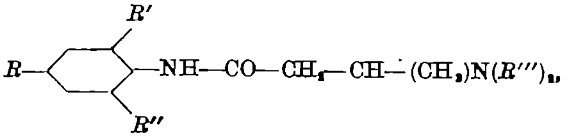
A New Type of Local Anæsthetic

Einhorn and Oppenheimer[1] more than fifty years ago synthesized a powerful local anæsthetic ('Nirvanin', the methyl ester of 3-diethylaminoacetylamino-6-hydroxybenzoic acid). Loefgren[2] prepared a similar compound ('Xylocain', 2-diethylaminoacetylamino-1-3-dimethylbenzene). Since this pioneer work in the field of local anæsthetics, many hundreds of effective compounds have been synthesized and tested; for a literature review on the subject, see Buechi, "Die Entwicklung der Arzneimittelforschung auf dem Gebiet der Lokalanaesthetica"[3].

A new series of compounds[4] of the type



where R = H or alkoxy, R' = H, CH_3 or alkoxy, R'' = H or CH_3, R''' = CH_3 or C_2H_5, has been prepared and shows marked local anæsthetic activity. One member of this series ($R = OC_2H_5$, R' and R'' = H, $R''' = C_2H_5$) was more active in guinea pigs than procaine and showed about half the toxicity in acute toxicity tests on mice. The other members prepared to date show approximately similar pharmacological properties to procaine, although their acute toxicity varies widely. Where R = H, R' and R'' = CH_3, $R''' = C_2H_5$ the toxicity in mice rises to about twenty times that of procaine.

Early attempts were made to synthesize the series from β-brombutyric anilide and dialkyl amines but resulted only in the formation of the anilide of crotonic acid. Treatment of this anilide, however, with excess amine under pressure gave the required substances in good yield.

Treatment of these β-dialkylaminobutyric anilides with concentrated hydrochloric acid yielded the corresponding aniline hydrochlorides and β-dialkylaminobutyric acid, thus establishing the position of addition of the amino group.

Full details of the chemistry and pharmacology of the series will be published elsewhere in due course.

Sepsis and Cortisone

THAT cortisone is able to suppress the inflammatory reaction irrespective of the nature of the causative agent is now a generally accepted fact. The site at which it is able to exert this effect remains uncertain; but it has recently been shown that cortisone can prevent or nullify an increase in capillary permeability[1], and that its administration is associated with an increase of arteriolar tone[2]. The latter authors consider that these two vascular effects are the most significant factors in the modification of the inflammatory processes.

In order to ascertain whether the effects of cortisone in acute inflammation would be consistent with such a view, we have investigated its influence in pyogenic infection. Eight rabbits were given an intracutaneous injection of 0·1 ml. of a 24-hr. broth culture of a coagulase-positive staphylococcus. Five of the rabbits received intramuscular injections of 10 mgm. cortisone acetate daily during the period of the experiment (commencing 24 hr. before infection) and three animals served as controls. The rabbits were killed on the fourth day after infection; the affected area of skin and subcutaneous tissue was excised, and serial paraffin sections were cut and examined.

There was a marked difference between the appearance of the resulting lesions in the test and control animals, those receiving cortisone showing a sharply demarcated chancroid nodule, in contrast to the less circumscribed fluctuant lesion exhibited by the control. The most striking feature observed, however, was the absence in the cortisone-treated animal of the normal polymorphonuclear infiltration and associated tissue necrosis, which was replaced by a dense mononuclear infiltration with minimal tissue destruction. An additional finding of considerable significance was the complete absence of organisms in the lesions of the test rabbits, whereas all control animals showed their presence in large numbers.

Our findings suggest that the suppression of the inflammatory reaction enables the organisms to disseminate rapidly, as has been observed by Lewis[3] and Antopol[4]. This dispersion from a small focus might be responsible for the severe infections described by Seyle[5] and by Gledhill and Rees[6] in animals treated with cortisone.

Two possible explanations can be advanced for failure to localize the infection: either no inflammatory fibrin barrier is formed and the bacteria are carried away by lymphatic flow, as suggested by Seyle[5], or changes at the vessel wall arrest leucocytic diapedesis and so prevent phagocytosis. Both these factors are probably at work. The mononuclear infiltration, not being entirely dependent upon diapedesis, arises through proliferation or migration in the adjacent tissues.

The absence of necrosis in the cortisone-treated lesions may be attributed to the absence of polymorphonuclears and of exudate containing proteolytic enzymes.

All the above effects of cortisone are more readily and simply explained by an interference with the vascular phenomena of inflammation, as suggested by Ashton and Cook[2], than by postulating its intervention at some other stage. This view is supported by the observations of Moon and Tershakovec[7], who have shown that cortisone does not effect the margination of leucocytes in an inflammatory lesion.

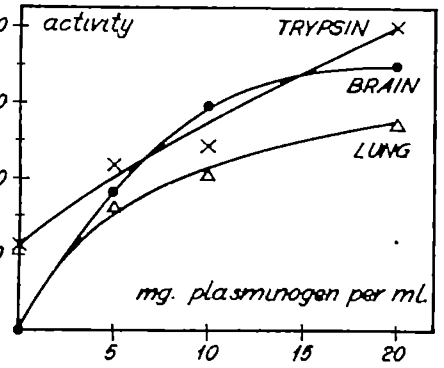
Fibrinolytic Activity of Tissue Extracts and of Trypsin

Macfarlane and Biggs[1] have reported on fibrinolytic enzymes in extracts of human tissues. The recent isolation of a soluble fibrinolytic activator from washed and dehydrated pig heart tissue[2] suggested a re-investigation of the fibrinolytic activity of such tissue extracts.

Saline extracts were prepared from the ground tissue from human lung and pig brain. The extracts were very active when estimated by the standard fibrin plate method[3], where the substrate (bovine fibrin) contains plasminogen. No fibrinolytic effect was observed when the extracts were tested on fibrin plates in which the plasminogen had been destroyed by heating as described by Lassen[4]. However, an effect was obtained when bovine plasminogen was added to the extracts, the size of this effect depending upon the amount of plasminogen applied (see graph).



Fibrinolytic effect of pig brain extract, human lung extract and crystalline trypsin on plasminogen-free fibrin when the concentration of bovine plasminogen in the active solutions is varied Abscissa · Concentration of the plasminogen preparation in the sample Ordinate · Activity recorded as the diameter product (in mm ²) of the lysed zones

It is evident that the fibrinolytic agent contained in these extracts is an activator of plasminogen and not a fibrinolytic enzyme proper. It may be recalled that in extracts prepared from heavily disintegrated tissue (Potter homogenizer, Waring blendor) the fibrinolytic activity is caused by an activator present in the small particles[5].

In similar experiments the effect of plasminogen on the activity of a number of proteolytic enzymes was investigated. An increase in plasminogen concentration had only a slight effect on the activity of chymotrypsin (cryst., Armour), of an *Aspergillus* protease obtained from Dr. W. G. Crewther[6], of a proteinase from *B. subtilis* (obtained from Prof. K. Linderstrøm-Lang, Copenhagen) and of bovine plasmin (prepared by activation with fibrinokinase or spontaneously[7]). However, when trypsin (cryst., Armour) was added, an enormous increase in activity was produced when the concentration of plasminogen was increased (see graph).

Trypsin, therefore, in addition to its effect as a proteolytic enzyme, appears to act as an activator of plasminogen. Most probably this activation depends upon a partial proteolytic splitting of the plasminogen molecule. This action resembles the known effect of trypsin in blood clotting, by which prothrombin is converted into thrombin.

This investigation has been aided by a grant from the Josiah Macy, jun., Foundation, New York.

Migration and Gregarious Æstivation in the Bogong Moth, *Agrotis infusa*

IN 1834, Bennett[1] reported immense aggregations of the bogong moth, *Agrotis infusa* (Boisd.) (Noctuidae, Lep.), in the clefts and small caves of granite outcrops on mountain-tops in southern New South Wales. There the aboriginal tribes congregated to feast upon these moths, which constituted a valuable fat-rich food. Scott[2] and others confirmed these observations, but no satisfactory explanation for the moth assemblages has been offered.

Aggregations of *A. infusa* have been studied during the past two summers at several sites, between 4,000 ft. and 6,000 ft., on the Brindabella Range in the Australian Capital Territory. Moths began to assemble on the mountain tops late in October and the populations reached a maximum before mid-December. In late November, a large unidirectional flight in a southerly direction was observed at a point four miles north of the chief observation site, Mt. Gingera (6,092 ft.). There was no major decline in populations before the end of March, when all the moths disappeared. In early April, another large unidirectional flight, this time in a northerly direction, was observed near Mt. Gingera.

Strongly gregarious behaviour was indicated by the layer of moths which covered, in a compact imbricated pattern, large irregular areas of the rock surfaces in the crevices and caves. For about one hour night and morning, just after sunset and before sunrise, a small proportion of the moths became intensely active and many indulged in a milling flight over the summit of the mountain, even when the outside air temperature was 7 0° C. At no time during these periods of activity was copulation or feeding observed. Dissections of a hundred female moths taken from the caves at weekly intervals throughout the summer showed that spermatophores were never present in the bursa copulatrix, where they are normally deposited during copulation. Without exception the ovaries were immature and the fat body well developed. Although sugary food was apparently not sought, water may have been ingested from rock surfaces moistened by rain or dew. In the laboratory, moths taken from the assemblages at Mt. Gingera neither copulated nor laid fertile eggs when fed water alone but did so when fed a sucrose solution. Some 10,000 moths, confined to a small cave on Mt. Gingera by means of wire gauze on January 10, behaved in a similar manner to uncaged moths and did not attempt to escape until the end of March when the main moth populations had departed. Again, dissections of samples of the caged females taken at intervals showed that copulation had not taken place and the ovaries were undeveloped.

It seems clear that adults of the spring generation of *A. infusa* migrate in swarms to the mountains, where they æstivate gregariously. At the end of March the moths again migrate, presumably to their breeding grounds. Careful search has not revealed larvæ of this species in the vicinity of the adult æstivation sites although suitable food plants are abundant. The larvæ have, however, been recorded as pests of field crops and pastures over a wide area of the tablelands and western slopes of New South Wales, and in other southern States.

Although migration is now known to occur in many Lepidoptera, *A. infusa* is believed to be the first species in which gregarious æstivation following spring migration has been reported. The monarch butterfly (*Danaus plexippus* (L.)) of North America migrates south during the autumn to hibernate gregariously in southern California and in Florida, migrating north again in the spring[3]. Pepper[4] suggested that the sudden disappearance of the noctuid, *Chorizagrotis auxiliaris* Grote, from Montana and Alberta with the approach of summer may be due to migration to higher elevations where æstivation may be possible at lower temperatures. In Egypt and India, *Agrotis ypsilon* (Rott.) is believed to migrate northwards to the mountains for the summer months[5], but there have been no reports of æstivation.

Detailed results of these studies will be reported elsewhere.

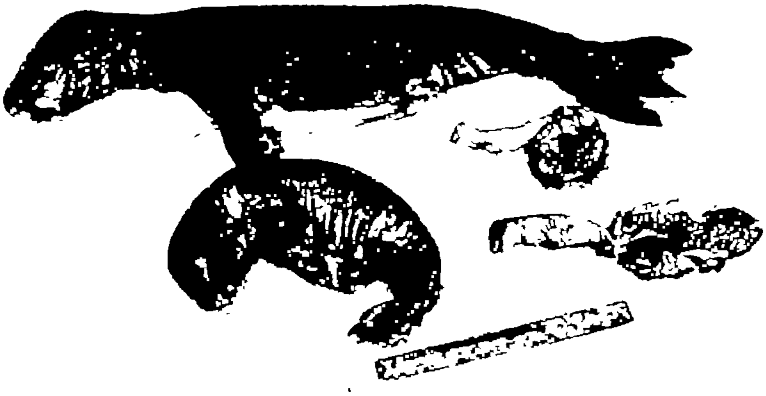
Observations on the Newly Born Leopard Seal



(A.N.A.R.E. Photo)

Leopard seal foetuses aged 2½, 3, 5 and 7 months respectively

PART of the biological research of the Australian National Antarctic Research Expedition at Heard Island during 1951 was aimed at solving the unknown factors about the leopard seal, *Hydrurga leoptonyx* (De Blainville). The rate of fœtal growth for the complete gestation period was investigated and specimens were obtained from February onwards. No newly born pup had previously been seen, because the pregnant females migrate during September–October to the southern pack-ice where the pup is born. To overcome this difficulty, the men at Heard Island constructed a large mobile cage and drove a pregnant female leopard seal into it on September 12 1951. Every three or four days the cage was dragge into the sea at low tide and left for the rest of the day The seal would not feed during captivity, but it wa noticed that she drank large quantities of sea wate on being placed in the ocean.

Some days before pupping, the female assumed characteristic position, lying on its side. Uterine an vaginal contractions were easily discernible an movements of the fœtus reached a maximum as th date of birth approached. Contractions were sometimes accompanied by moaning noises and considerable restlessness. Whether or not parturition was rapid process is unknown since, in this case, birt occurred unseen between 9 p.m. and 6.45 a.m. o November 14.

From the position of the mother, pup and placenta it is assumed that the pup was born head first in manner similar to the sea elephant and the othe three Phocids. The umbilical cord attached to th placenta was probably broken by the pup in it movements and remained as a stub about 4 in. i length. The newly born pup was 62 in. in length an weighed 65 lb.

Measurements were :

Flipper length (inside)	16 in.	Girth before tail	19 i
Tail flipper length (inside)	16 ,,	Neck circumference	17 ,
Girth behind flippers	24 ,,	Width at flippers (ventral)	12 ,

The eyes were open at birth and the adult dentitio was well developed, the tips of the canines and on incisor being visible externally. The placenta showe no special peculiarities and weighed 6 lb.

The behaviour of the parent to the pup after birt must be regarded conservatively in this case, sinc the pup was dead during its observation. Two fact are apparent, however : first, the mother was affe tionate towards the pup and indignant at intrusion and secondly, she displayed a definite desire to kee the pup warm. This latter point was most noticeabl the mother lying alongside the pup and keeping th closest possible contact with it.

The birth of the sea leopard pup would appear follow the pattern of parturition in other types seals. The advanced developmental stage of the adu dentition indicated that the period of lactation wou be very short, probably from ten to fourteen day If the rate of growth followed the trends of oth

Phocids, the pup would have a weight of about 125 lb. at weaning.

Apart from rate of fœtal growth, many other investigations were carried out. The milk dentition, which it reabsorbed before birth, was ascertained by taking X-rays of fœtuses. More than a hundred animals were branded and their movements studied for migration, etc. All the information is now being prepared for a comprehensive paper on the biology of the leopard seal.

Terramycin in the Treatment of Experimental Rabies in Mice

The following experiment was carried out to test the value of terramycin[1] in the treatment of experimental rabies in mice.

The strain of rabies virus used in this experiment was Paris fixed strain. It was obtained in 1935 from the Public Health Laboratories in Jerusalem. Since that time it has been maintained in rabbits and sheep and used in these laboratories for the routine preparation of antirabic vaccine. It never failed to produce paralytic rabies in sheep, rabbits and mice in 6–7 days. Its potency is such that the L.D.50 for mice, calculated by the method of Reed and Muench, is $0 \cdot 03$ ml. $\times 10^{-5}$ brain emulsion[2].

The mice used were albino Swiss mice which were originally obtained from Dr. Mahaffy, of the Virus Reference Laboratory, Entebbe, and bred locally in Khartoum for the past twelve years. The average age of the mice used in this experiment was three weeks. Each mouse was weighed and the dose of terramycin required was calculated. Each mouse received 150 mgm. of terramycin per kgm. body-weight twice daily with an interval of four hours between the two doses.

Crystalline terramycin hydrochloride in capsules manufactured by Chas. Pfizer and Co., Inc., was used. The contents of one capsule (250 mgm.) were put in a 100-ml. conical flask and 25 ml. of McIlvaine's phosphate–citric acid buffer solution, *p*H 7·0, added. The flask was then shaken thoroughly until a fine emulsion was obtained. A fresh preparation was made daily and kept at 4° C. in the refrigerator until required.

Three groups of mice each consisting of ten mice were used. Each mouse was lightly anæsthetized with ether and then injected intracerebrally with 0·03 ml. of 1 per cent brain material emulsified in normal saline. Group 1 was left without further interference to serve as controls. Group 2 was treated with intramuscular injections (150 mgm. per kgm. body-weight) of terramycin twice daily. Treatment was started half an hour after the intracerebral injection, repeated four hours later and continued twice daily for six days. Group 3 was similarly treated with terramycin for six days, but the intraperitoneal route was used in this group.

On the sixth day of injection, all the thirty mice in the three groups developed paralysis, which started in the hind legs and then became generalized. The mice died of typical paralytic rabies on the sixth or seventh day. No difference whatsoever was noted between the mice treated with terramycin and the untreated control mice, either in the incubation period or in any other feature of the disease. Hence we conclude that terramycin has no value in the treatment of experimental rabies in mice.

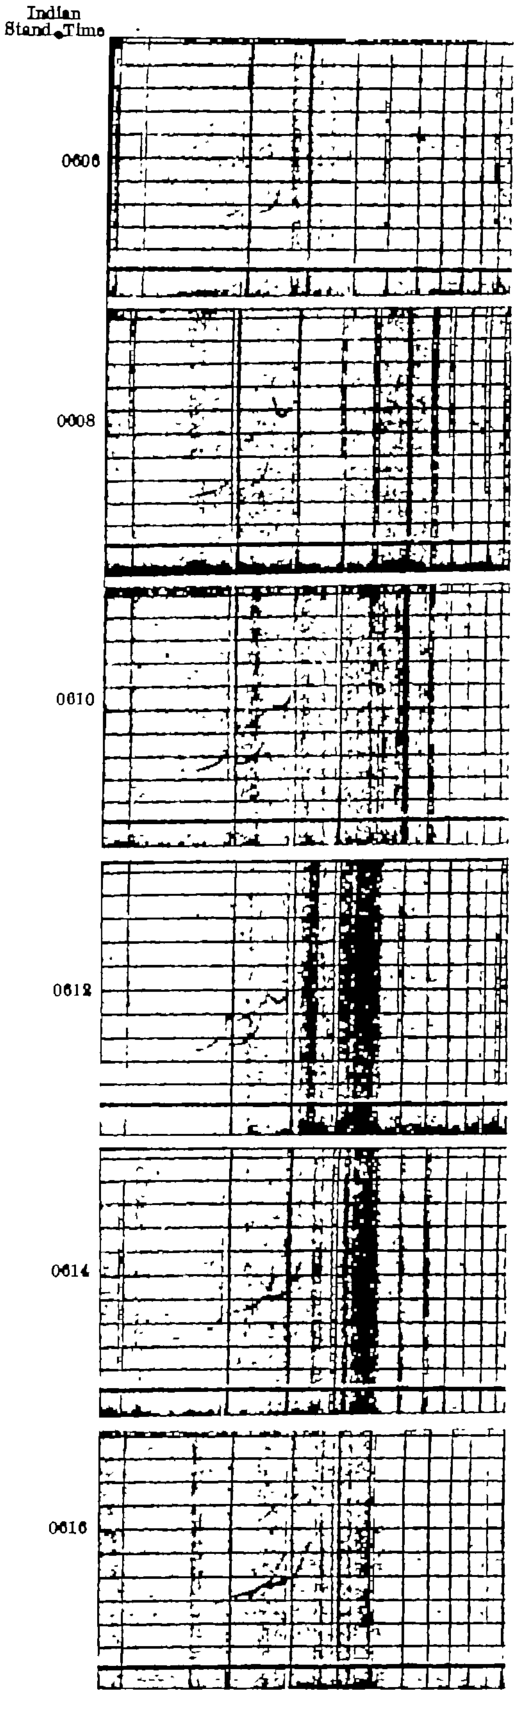
A New Early-Morning Ionospheric Phenomenon

Early in January 1952, when ionospheric observations were started at Kodaikanal (10° 14′ N., 77° 28′ E.), an interesting phenomenon, which, to my knowledge, has not hitherto been reported, was observed in the vertical-incidence virtual height/critical frequency records. It was found that on most of the mornings ionospheric echoes ceased to return some minutes to several hours before sunrise and reappeared at about ground sunrise time. Systematic daily observations were started early in March and *h′f* records taken at short intervals beginning about an hour before sunrise daily with the view of examining the frequency of occurrence and any possible seasonal characteristics of this 'no echo' phenomenon.

The observations consisted in photographing the *h′f* patterns at 1- or 2-min. intervals with the *C.R.P.L.* type *C*-3 recorder of the Kodaikanal Observatory covering 1–25 Mc./s. and with peak pulse power of approximately 10 kW. The antenna system consisted of two multiple-wire deltas having reasonably flat impedance over the operating frequency-range and the desired vertical direction of maximum radiation. The records thus made cover a period of five months (March–July 1952) and on examination indicate that on about 60 per cent of the days during these five months ionospheric echoes ceased for some time during the pre-dawn period. The overnight stratum in the *F*-region present at virtual heights of 200–300 km. disappeared gradually without showing any appreciable sharp drop in critical frequency (which is of the order of 1–3 Mc./s. during early mornings). The 'no echo' condition lasted until about the ground sunrise time, when reflexions began to be received from markedly greater virtual heights of 300–500 km. Records taken at 15-min. intervals on the morning of April 30, 1952, show that pulse returns ceased between 0500 and 0515 hr. and did not begin again until shortly before 0545 hr. (All times are given in Indian Standard Time, which is 5 hr. 30 min. ahead of G.M.T.)

On other mornings when ionospheric echoes were received throughout, high-speed ionospheric soundings showed remarkably characteristic sunrise effects in the *F*-region. Almost simultaneously with the ground sunrise, a stratum formed somewhere between 300 and 600 km. The virtual height of the new stratum decreased rapidly until it merged with the overnight layer, usually present at a virtual height of about 200–250 km. The accompanying photographs are of a sequence of *h′f* records obtained on one such morning; they were taken at 2-min. intervals on March 9, 1952, and illustrate the characteristic sunrise effect observed at this location.



A study of sunrise effects in the ionosphere has been made by Wells[1] at Derwood Experimental Laboratory, D.T.M., Carnegie Institution of Washington. Sunrise effects have been defined as the initial characteristic rise of ion density in the neighbourhood of sunrise. At Kodaikanal, the abrupt appearance of echoes from relatively great virtual heights, such as shown in the records for March 9, 1952, has enabled the determination of the precise times of these effects. A study of successive $h'f$ records at 1- or 2-min. intervals on selected days when such records were available indicates that, notwithstanding a certain amount of scatter, the sunrise effect and the ground sunrise were simultaneous during the month of March; during April, the ionospheric effect occurred 2 min. after the ground sunrise, and during May, June and July it occurred 3½ min., 6 min. and 5 min. respectively before the ground sunrise.

I wish to thank Dr. A. K. Das, director of the Kodaikanal Observatory, for his advice in writing this note.

Automatic Particle-Sizing by Successive Countings

Walton[1] has recently summarized informal discussions among workers in Great Britain on methods for the automatic counting and sizing of particles dispersed on microscope slides. The field is normally scanned with a beam of light, and the changes in transmission or reflexion as the scanning beam (for example, a slit or a spot) encounters particles, or parts of particles, are detected photoelectrically. The quantities that can be measured are the pulse-heights (related to the areas of the particles), the pulse-lengths (related to the lengths of particles) and the number of pulses. Methods of counting have been based on measurements of the number of pulses occurring in the area swept by the scanning aperture; but all proposals for sizing have been based on the measurement of pulse-heights or pulse-lengths. It is the purpose of this communication to point out that sizing also can be carried out by recording only the number of pulses. The relatively simple instruments designed for counting can therefore be employed for sizing.

It is obvious that if the geometry of the scanning aperture or the response-level of the detecting device can be arranged so that the number of pulses recorded is dependent on the size of the particles, then the size distribution can be obtained by repeated counting with different scanning apertures or response-levels. For example, if the field is scanned with a slit and a count is recorded only when the slit is totally obscured, the number of pulses recorded is clearly dependent on the size of the slit relative to the size of the particles; there will be no count for a very large slit, whereas every particle in the scanning track will produce a recorded pulse with a sufficiently small slit. In the general case, the scanning aperture may have any shape and any orientation relative to the direction of scan or may consist of several apertures such as a pair of scanning spots. In addition, the response-level of the detecting device may be set to any finite value.

In one of the simplest applications, the field is scanned, not necessarily systematically, with a slit of width w (perpendicular to the direction of scan) which is varied in repeated scans from w less than a, the size of the smallest particle present, to w greater than b, the size of the largest particle. The number of times, $m(w)$, the slit is totally obscured in unit length of scan is recorded for each of several scanning track widths, w. If the number of particles (of all sizes) per unit area of the field is N, it can be shown that the size distribution is given by $1/N$ times the second derivative of the observed frequency distribution $m(w)$.

An alternative method, especially suitable for use with the 'flying-spot' microscope[2], is to scan the field with two spots (each smaller than the smallest particle present), the distance apart of which, w, is similarly varied over the range a–b in repeated scans of the field. The frequency $m(w)$ is the number of times per unit length of scan that both spots are simultaneously obscured. It is not necessary, however, to provide separate detecting devices for the two spots or coincidence circuits for recording simultaneous pulses. It can be shown that $m(w)$ is equal to the difference between *twice* the number of pulses observed with a *single* spot (in a separate scan) and the number of times that two spots encounter particles simultaneously or separately. The latter number is measured by a single detecting device behind the two spots, so that simultaneous interceptions produce only single pulses.

The theoretical treatment, although simple, can only be outlined here. A slit describing a scanning track of width w across a field of particles intercepts, in unit length of track: m_1 whole particles of size d less than w; $2m_2$ part particles of any size overlapping one or other edge of track; and m_3 part particles of size d greater than w lying right across the track. Since the number, $m_2 + m_3$, of particles lying on either edge of the track is, on the average, equal to the number per unit length occurring in a strip of width given by the average particle size $\overline{d}$, the effective width of the scanning track is $w + \overline{d}$. We have also that $m_2 + m_3 = N\overline{d}$. Thus, the number per unit area is $N = (m_1 + 2m_2 + m_3)/(w + \overline{d})$, and hence

$$\overline{d} = (m_2 + m_3)/N \text{ and } N = (m_1 + m_2)/w.$$

These relations, being independent of the particle-size relative to the slit-width, are applicable to particles of any given size d when N and m refer to the numbers of that size. The relation above between $m(w)$ $(= m_3(w))$ and the size distribution follows readily. There are corresponding relations for $m_1(w)$ and $m_2(w)$. The significance of the 'size' measured cannot be discussed here, but it may be noted that the average size $\overline{d}$ is the average Feret diameter, which Walton[4] has shown, for particle-shapes having no re-entrant angles, to be equal to the perimeter diameter (the diameter of a circle having the same perimeter as the particle).

The number of particles per unit area, N, and also the average size $\overline{d}$, can be found by several methods. For example, with a slit of width w, the number of pulses per unit length is $m_1(w) + 2m_2(w) + m_3(w) = N\overline{d} + Nw$; and N and $\overline{d}$ may be deduced from measurements with two slit-sizes or with a slit and a guard spot. The slits may be of any size and need not be larger than b, as Wolff[3] implies. Again, with two spots at a spacing w less than a, the number of pulses is $2m_2(w) + m_3(w)$; while the number of pulses for a single spot is $m_2(w) + m_3(w)$; the difference $m_2(w)$ is equal to Nw, since $m_1 = 0$ when w is less than a. This method is more general, and experimentally simpler, than the double-spot counting procedure described by Roberts and Young[5], which requires systematic scanning with two 'labelled' spots having separate detecting devices.

Experimental investigations are in progress, and a full account will be published elsewhere.

Four-strand Crossing-over

T. C. Carter and A. Robertson, in a recent publication[1], have discussed a model of genetical interference in diploids, introducing explicitly postulated components of chiasma and chromatid interference. It appears, however, that their work is accompanied by certain misconceptions and erroneous pronouncements.

Carter and Robertson object to my view[2,3] that in many situations it is unnecessary to consider explicitly the detailed interaction of the four strands of a meiotic bivalent in bringing about genetical recombination. Such situations are those in which the observed frequencies are determined only by the probability distribution of exchange points on a single strand. The great majority of genetical studies on diploids do, in fact, relate to such situations, and it is much more rarely that an organism provides evidence concerning the simultaneous distribution of the exchange points on two, three or four strands of the same bivalent. Consequently, attempts to set up *detailed* models of four-strand interaction will, in the majority of cases, necessarily require an abundance of *ad hoc* hypotheses which are incapable of verification from genetical data, and therefore impose artificial restrictions on theory, entailing an undesirable lack of generality.

With these considerations in mind, I asserted that in such cases (admitting only of the examination of single strands) it is sufficient in formulating a mathematical description to confine attention to the probability distribution of exchange points upon any single one of the four strands produced in meiosis. This view, which seems to me to express merely an exceedingly simple and obvious logical proposition, is regarded by Carter and Robertson as "unsupportable". They say that in my treatment I was tacitly employing a two-strand model, and was, moreover, describing the distribution not of exchange points but of chiasmata. There is, however, no foundation for these statements.

Since the major difficulty experienced by Carter and Robertson is a logical one, I would like to put forward a simple analogy. Suppose that a quality control inspector has to check the dimensions of aluminium rods. I, together with most people, would say that all he requires is a single specification applicable to any rod produced by the manufacturing process. Carter and Robertson would seem to insist that he be provided with a specification descriptive of batches of rods as produced simultaneously by the machines.

In my own treatment[2-4] I did, in fact, deal with four-strand recombination and *not* two-strand. I dealt with exchange points and not with chiasmata as Carter and Robertson assert. Further, I have given various formulæ which in my papers[2,3] are labelled explicitly as referring to exchange points. These have been quoted by Carter and Robertson (out of context) as referring to chiasmata. As I shall show, this course, which seems to have been adopted as a result of a primary misconception, is likely to lead to error.

My treatment was first developed in terms of an unspecialized interference function $f(t)$, relating to exchange point intercepts, which can be specialized in ways considered most likely to fit experimental data. At the next stage in the argument I selected a special form, $4te^{-2t}$, which remarkably unites two advantages. First, it is mathematically very convenient, and secondly has been found to accord well with empirical evidence[3-5]. Now it so happens that the *general* theory (prior to specialization) is formally applicable to chiasmata as well as to exchange points. But at the stage where specialization of $f(t)$ becomes necessary, I deliberately chose the form $4te^{-2t}$ as descriptive of exchange points and *not* of chiasmata. At a critical stage in the construction of their own model, Carter and Robertson find need to insert in their formula some theoretical chiasma statistics, and 'solve' this problem by taking over formulæ of mine (based on the function $4te^{-2t}$) which, in fact, were chosen by me as appropriate to exchange point statistics. No critical examination is made of the suitability of these formulæ with regard to empirical justification when applied to chiasmata. To say the least, this slip seems likely to impair the value of the mathematical structure they have erected.

I might add, in conclusion, that at the time my paper was published, I had investigated the compatibility of the function $4te^{-2t}$ with the mechanism of four-strand exchanges, and confirmed that it was consistent with a variety of models involving different intensities of chromatid and chiasma interference[5].

[5] Owen, A. R. G., Ph.D. dissertation, University Library, Cambridge (1948).

DR. A. R. G. OWEN has developed the mathematical treatment of linear sequential events. He applied it to the occurrence of exchange points in a gamete, that is, those chiasmata at the preceding meiosis in which the strand entering the gamete took part: chiasmata involving only other strands were not considered. To describe this as a four-strand model is true only in so far as three emergent strands are disregarded; it can equally well be described as a model with two, three or any number of strands. The resulting equations are formally identical with those of a two-strand model; for this reason chromatid interference, which is a multi-strand phenomenon and of which there is sound cytological evidence[1], cannot be distinguished from chiasma interference.

This model seemed to us biologically unsatisfactory; we therefore applied Owen's treatment of sequential events to chiasma formation in a four-strand model, which allowed an explicit treatment of chromatid as well as chiasma interference.

Computing Machine Terminology

IN a recent letter in *Nature*[1], Prof. R. O. Kapp raises a protest against the use of certain expressions current in the vocabulary of computing machine designers. The chief burden of Prof. Kapp's remarks is directed against the use of anthropomorphic terms, and it is perhaps of interest to see how these arose. The earliest idea for an all-purpose computing machine, in the modern sense, was due to Charles Babbage[2], who used the terms: mill = portion of machine which operates on numbers; store = portion of machine which holds numbers and emits or absorbs them at the direction of the machine.

When the actual construction of an electronic calculator was first considered, by von Neumann and his group, the logical design was made to depend, to a considerable extent, on what were, at that time, conceived to be the neurological mechanisms o animals. This led to the development of a nomenclature which had the characteristics deprecated by Prof. Kapp.

In fact, most designers (as distinct from the "enthusiasts" of Prof. Kapp) now favour a more down-to-earth vocabulary in which, for example, 'memory' is replaced by the less exceptionable word 'store'. On the other hand, Prof. Kapp is not correct in stating that the words 'setting' and 'adjustment' are synonymous with the 'instruction' and 'teaching' of computer parlance. Neither does the word 'readings' have much relationship to the 'information' given to a computer.

So far as Prof. Kapp's 'code' is concerned, this word is very widely used in computer technology, and the equivalent 'machine language' has been added by linguists and semanticists who have recently 'discovered' these machines.

It has not been possible, in a short note, to conside in detail the technical meaning of the words give above; but it is worth pointing out, in conclusion that the word 'decision'—or as we prefer it, 'conditional transfer of control'—does not necessarily impl that the machine follows a pre-determined sequen of events. On the contrary, the conditional transfe is frequently used in order that the machine shoul select between alternative courses of action in manner which may never become known to the huma operator.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, December 6

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne), at 2.30 p.m.—General Meeting.

Monday, December 8

Physical Society, Acoustics Group (at the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Mr. G. Bradfield: "Measurement of Elastic Constants of Solids".

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. E. Schrodinger, For.Mem.R.S., and Prof. Max Born, F.R.S.: Discussion of Prof. Schrodinger's paper "Are there Quantum Jumps?"

Manchester Literary and Philosophical Society (in the Reynolds Hall, College of Technology, Manchester), at 5.30 p.m.—Mr. W. B. Fagg: "The Nature of African Art".*

Society of Chemical Industry, Corrosion Group (joint meeting with the Yorkshire Section of the S.C.I., and the Sheffield Metallurgical Association, at the Grand Hotel, Leopold Street, Sheffield), at 6.45 p.m.—Dr. U. R. Evans, F.R.S.: "The Corrosion Resistance of Stainless Steels".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr G. W. Murray: "Land of Sinai".

Tuesday, December 9

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. A. H. Smith. "English Place-Names".*

Chadwick Public Lecture (at the Wright–Fleming Institute, St. Mary's Hospital Medical School, Norfolk Place, London, W.2), at 4.30 p.m.—Dr. A. I. G. MacLaughlin: "The Prevention of Dust Diseases of the Lungs" (Malcolm Morris Memorial Lecture).*

Institution of Mechanical Engineers, Automobile Division at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. H. E. Merritt: "The Place of Research in the Engineering Process with particular reference to the Automobile Industry".

Institution of the Rubber Industry (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. N. C. H. Humphreys: "Matching Rubber Compounds"; at 7 p.m.—Mr. G. F. Morton and Mr. P. Hatfield. "Recent Applications of Physics to Inspection Methods in the Rubber Industry".

Illuminating Engineering Society (at the Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Mr. H. C. Weston: "Visual Fatigue".

Society of Chemical Industry, Plastics and Polymer Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Discussion on "Bulk Polymerization".*

Wednesday, December 10

Royal Society of Medicine, Pathology and Medicine Sections (at 1 Wimpole Street, London, W.1), at 5.15 p.m.—Discussion on "Chemotherapy of Tuberculosis".

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Symposium on "Liquefied Petroleum Gases" (Mr. E. Squire: "Production"; Mr. S. Shaw: "Distribution"; Mr. T. H. Taylor: "Applications").*

British Institution of Radio Engineers, North-Eastern Section (at the Institution of Mining and Mechanical Engineers, Neville Hall, Westgate Road, Newcastle-upon-Tyne), at 6 p.m.—Mr. G. D. Clifford: "The Development of the Radio and Electronics Industry in India".

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "The B.B.C. School, Evesham" and "The Post Office School, Stone" (to be opened by Dr. K. R. Sturley and Mr. H. R. Harbottle).

Society of Chemical Industry, Nutrition Panel of the Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Discussion on "The Problem of Future World Food Supply". (Speakers: Mr. F. Le Gros Clark and Dr. E. W. Russell.)

Thursday, December 11

British Society of Rheology (at the Institute of Physics, Belgrave Square, London, S.W.1), at 2 p.m.—Symposium on "The Rheology of Foodstuffs".

Physical Society. Optical Group (in the Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Scientific Papers.

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. A. W. Merrison and Mr. E. R. Wiblin: "The Total Neutron Cross-section of Cobalt, Silver, Iodine, Aluminium, Nickel and Gallium between 1 eV. and 5 keV."; Mr. J. Dyson: "An Interferometer Microscope for Opaque Objects".

Royal Meteorological Society (in the Beveridge Hall, University of London, Senate House, Malet Street, London, W.C.1), at 5.30 p.m.—Dr. G. M. B. Dobson, F.R.S.: "The Upper Atmosphere". (Meeting is open to Sixth Form students.)

Friday, December 12

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Institution of Mechanical Engineers (joint meeting with the Applied Mechanics Group, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. Nicol Gross. "Experiments on Short-radius Pipe-bends".

North-East Coast Institution of Engineers and Shipbuilders (at the Literary and Philosophical Society, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. Hayne Constant, F.R.S.: "The Application of Research to the Gas Turbine" (David Laing Lecture).

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Mr. E. L. Streatfield: "Ion Exchange and its Application in the Fine Chemicals Industry".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. W. H. Pearsall, F.R.S.: "Habitat, Vegetation and Man".

Friday, December 12—Saturday, December 13

Universities of Great Britain and Northern Ireland (in the William Beveridge Hall, University of London, Senate House, Malet Street, London, W.C.1).—Conference.

Friday, December 12

At 2.30 p.m.—"Halls of Residence and Student Amenities".

Saturday, December 13

At 10.30 a.m.—"Success and Failure at the University"; at 2.30 p.m.—"Vacation Employment".

Saturday, December 13

British Psychological Society (in the Anatomy Theatre, University College, London, W.C.1), at 2.30 p.m.—Mr. Philip L. Short: "Some E.E.G. Findings in relation to Psychological Factors".

British Association of Chemists (at the Waldorf Hotel, Aldwych, London, W.C.2), at 3 p.m.—Thirty-fifth Annual General Meeting

---

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Bacteriologist (honours graduate, preferably with research experience) to work on problems of hygiene in the dairy industry—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 52/15 (December 13).

Lecturer in Chemistry at the Technical College, Coatbridge—The Director of Education and Deputy County Clerk, Lanarkshire House, 191 Ingram Street, Glasgow, C.1 (December 13).

Scientific Officer (with an honours degree in biochemistry or physiology) in the Nutrition Department, to take part in work that will include the determination of the biological value of proteins, the study of calcium and phosphorus metabolism using radioactive tracers, vitamin D assays and general nutritional experiments with rats—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 52/14 (December 13).

Supervising Geophysicist to be responsible for the supervision and direction of all field, laboratory and office operations regarding geophysical prospecting for radioactive minerals, a Senior Geophysicist to take charge, under direction, of field, laboratory and office investigations of a group engaged in air-borne scintillometer survey, a Geophysicist (Grade 3) to take charge, under direction, of a party engaged in the field and/or laboratory on radio-metric investigations in connexion with the search for deposits of radioactive minerals, a Geophysicist (Grade 2) to carry out, under direction, field, laboratory and office investigations concerning deposits of radioactive minerals; a Supervising Geologist to be responsible for the supervision and direction of field operations of the radioactive group of the metalliferous deposits sub-section, a Geologist (Grade 3) to carry out, under direction, the more advanced types of petrological and mineralographic investigations and compile reports thereon, or to take charge, under direction, of a party engaged in the geological mapping of deposits of radioactive minerals, a Geologist (Grade 2) to carry out in the field, under direction, mapping of deposits of radioactive minerals, and assist in the preparation of reports; in the Bureau of Mineral Resources, Geology and Geophysics, Australia—The Deputy High Commissioner, Australia House, Strand, London, W.C.2, endorsed 'for attention of The Senior Representative, Division of Industrial Development' and stating position applied for (December 20).

Fellowship in Pure or Applied Mathematics—The Registrar, Trinity College, Dublin (December 31).

Senior Lecturer or Lecturer in Physics at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 15 Victoria Street, London, S.W.1 (January 1).

Statistician in the Department of Agriculture and Horticulture at Long Ashton Research Station—The Registrar and Secretary, The University, Bristol 8 (January 3).

Lecturer in Physical Chemistry at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 17).

Biochemist at the South Devon and East Cornwall Hospital, Greenbank Road, Plymouth—The Group Secretary, Plymouth, South Devon and East Cornwall General Hospital Group, 7 Nelson Gardens, Stoke, Plymouth.

Chemist (Senior Scientific Assistant) at the Central Laboratory, Chiswick, with responsibility for section dealing with paints and surface protection—The Staff Officer (F./EV.223), London Transport, 55 Broadway, London, S.W.1.

CHEMISTS at Ministry of Supply research establishments in Southern England for (*a*) work in laboratory providing chemical services, including effluents testing, process control, and boiler-water treatment (industrial experience desirable), (*b*) inorganic analysis (experience of radiochemistry desirable), (*c*) general chemical work (some experience of paint technology of advantage), and (*d*) physical chemistry research—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting E 735/52A.

ELECTRICAL ENGINEER for the Central Electrification Scheme, Cyprus—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M 29024 B.

PLANT PATHOLOGIST (with honours degree in botany and at least two years' postgraduate experience), Nyasaland, for advisory and investigational work, mainly at Lilongwe Research Station—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CSC.63/4/01.

PRINCIPAL—The Clerk to the Governors, Loughborough College of Technology, Loughborough

SCIENTIFIC OFFICERS (with first- or second-class honours degree, or equivalent, in physics, engineering or mathematics) for operational research on a wide variety of problems in London and provinces, under direction of Scientific Adviser to the Air Ministry—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.285/52A.

SILVICULTURAL ECOLOGIST (with good honours degree with two years' postgraduate experience which must include work on soils) in Malaya, for research in the reclamation of degraded soils and waste-land, to restore fertility and productivity, possibly by introduction of suitable forest cover—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CSC.87/60/01

EDUCATION AND TRAINING OF METALLURGISTS

A JOINT Committee on Metallurgical Education was formed in 1945 by the councils of the Iron and Steel Institute, the Institution of Mining and Metallurgy, the Institute of British Foundrymen, the Institute of Metals and the Institution of Metallurgists to advise them on all matters concerning metallurgical education in the United Kingdom. This Committee has previously issued two reports ("Qualifications for Entrance to University Schools of Metallurgy" (February 1948) and "Recommendations on University Full-time Degree Courses in Metallurgy" (1950)) dealing with the university education of metallurgists, and has now issued a third* which covers the whole field of metallurgical education and training, ranging from the training of operatives in the techniques they practise, to the university education and subsequent training in industry of the highest grade of professional metallurgists. The view expressed in an earlier report that "The Universities are at present, are likely to be and should continue to be the chief source of high-grade technologists" is reaffirmed, and the university schools are urged to expand their output to the utmost of their ability. In line with a growing feeling in industry, it is recommended that university courses in metallurgy should provide education in management and administration, and that undergraduates reading metallurgy should have more opportunity for contact with cultural and humanistic subjects. These are important and significant recommendations which may well point the way which university courses in metallurgy will follow during the next few years.

So far as industry is concerned, the Committee makes two recommendations with regard to graduates. The first is that employers should make the fullest possible use of postgraduate studies available in Britain by financing attendance of suitable employees at one of the recently established Postgraduate Schools of Metallurgy at Birmingham or Sheffield. The second is that formal methods for training graduates immediately they enter industry should be adopted more widely.

Undoubtedly the most important part of the report, and one which is likely to influence future developments most profoundly, is that which is concerned with technologists who obtain their education by part-time study. It is probably not going too far to say that such men are the backbone of the metallurgical industry in those regions of Great Britain where, for many years, there have been part-time courses leading ultimately to a local 'associateship' of a very high standard. Unfortunately, not all regions have provided equal educational facilities; unfortunately, too, not all students have been able to complete the course, and the unsuccessful ones have received no formal qualification when they have reached the limit of their capabilities. The Joint Committee now recommends the rationalization of such part-time education on a national scale, with corporate membership of one of the professional metallurgical institutions (generally the Institution of Metallurgists) as the ultimate goal of all technological pupils in metallurgy. Thus, the Ordinary and Higher National Certificates in Metallurgy and the licentiateship and associateship of the Institution of Metallurgists could be successive rungs on the ladder for those aiming at becoming professional metallurgists by part-time study. The education of such men would be the responsibility of the colleges of technology and the technical colleges, and the report suggests a number of steps that should be taken to enable these institutions to play their part more effectively.

---

* The Education and Training of Metallurgists. A Report of the Joint Committee on Metallurgical Education of the Iron and Steel Institute, the Institution of Mining and Metallurgy, the Institute of Foundrymen, the Institute of Metals and the Institution of Metallurgists. Pp. 56. (Joint Committee on Metallurgical Education, 4 Grosvenor Gardens, London, 1952.)

The Committee takes the view that at present the technical colleges of Britain as a whole are not making an adequate contribution to the stock of high-grade technologists and quotes figures in support. It considers that these colleges must be made into better teaching institutions by raising the present standard of staffing. ". . . The provision of good teaching-staff is the first essential in improving the output of high-grade technologists. Compared with this, such matters as technological universities, institutions of technology and degrees in technology are relatively unimportant. . . ." It is a sad reflexion on the present position that the Committee finds it necessary to say that ". . . all who teach technological metallurgy should have been trained and become qualified in the theory and practice of the subject. . . ."

A number of clear recommendations are made on the measures that should be taken to enable the technical colleges to attract staff of the necessary high quality. The difficulty is not a financial one, for salaries in technical colleges are, on the whole, comparable with those in the universities; it is much more likely that the conditions of work are not sufficiently attractive. At present most technical colleges are responsible for the instruction of both technicians and technologists. It is recommended that these two functions should be separated and that instruction in metallurgy at a high level should be restricted to a few selected colleges in the important centres of metallurgical activity, such as London, Birmingham, Glasgow, Manchester, Sheffield, either Cardiff or Swansea and either Newcastle upon Tyne or Middlesbrough. Such colleges would be concerned purely with technology and would be fed with students by the remaining technical schools and colleges, which would be responsible for less advanced teaching

Much has been said in recent years about the desirability of research being done in the technical colleges, but little progress can be made in this direction if the teaching staffs are overburdened with teaching; the Joint Committee urges that the staffs of technical colleges should be given real opportunities both for research and for spending periods in industry from time to time to keep up to date with developments in industrial technology.

Where the training and education of technicians and operatives are concerned, the report is less definite. The work of the British Iron and Steel Federation in this field is highly praised, and the non-ferrous industry is urged to adopt properly planned training courses on similar lines. Employers are advised to give a real incentive to study by making it known that in filling leading technical positions in the productive departments they would take into account any awards which a candidate had acquired from a recognized educational authority.

The report as a whole is readable and can be recommended to all who are interested in technological education. Those who read it will realize that, as might be expected, the Committee is familiar with conditions in industry and with the educational facilities in Great Britain. The majority of the recommendations are likely to receive widespread acceptance; and they must be given careful consideration by all those who are concerned with the education or training of metallurgists. The views expressed on the technical colleges are realistic, and of particular interest in the light of recent discussions on the need in Britain for a university of technology.

BOTANICAL ASPECTS OF THE FORM PROBLEM

Morphogenesis in Plants

By Prof. C. W. Wardlaw. (Methuen's Monographs on Biological Subjects.) Pp. xi+176+4 plates. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1952.) 10*s.* 6*d.* net.

THIS is a small book about a very large subject. Morphogenesis is a much more familiar word than it was not many years ago, and the discipline it denotes is coming to be recognized as one that involves in its pursuit all the major fields of biological science, culminating in an attempt to explain the integrated 'wholeness' of the organism. The present volume is an examination of some of its problems that are exemplified in the development of the higher plants.

A distinctive feature of these plants is that much of their growth takes place through the activity of meristems. These regions, and particularly the apical meristem of the shoot, provide experimental material for a study of plant morphogenesis somewhat analogous to the young embryo in corresponding studies of animal development. It is this apical meristem with which Prof. C. W. Wardlaw's own work has been particularly concerned, and it naturally occupies a conspicuous position in his book. The author describes with clarity the structure of these growing points and the development of lateral organs from them, together with some of the delicate and beautiful experiments that he and others have performed there.

Emphasis on this aspect of morphogenesis has necessitated the omission, or a much abbreviated treatment, of some others that are also important The present reviewer would like to see in such a book as this a somewhat fuller presentation of the basic facts of differentiation, polarity, symmetry regeneration and teratology, for example, together with the morphogenetic problems raised by these phenomena. The discussion of the various factors involved in the control of plant development is also somewhat unbalanced. The author devotes a good deal of space to growth substances and to the action of genes; but very much less to such important factors as light, temperature, water relations, inorganic chemical substances and mechanical influences. Even to state all the many and varied problems of plant morphogenesis within the limits of a book as small as this one is obviously impossible; but there is danger that an inexperienced reader will get from it a rather one-sided picture of the subject as a whole.

At a time when biologists so strongly emphasize the purely chemical factors in development, it is refreshing to read the author's statement that "a knowledge of chemical processes alone, however precise and detailed it may be, does not and cannot tell us how a particular form comes to be assumed", but that "it is to biophysical and other physical forces . . . that we should look for the immediate or proximate cause of the specific form or structure". Most thoughtful students of the subject will agree with these conclusions.

The author does not minimize the profound complexities which still confront morphogenetic research. "It is a chastening thought," he remarks, "that after so many decades of work, our knowledge of the factors which determine the form of these organs (leaves) is still as incomplete as it proves to be." This might well be said of all the structures of the plant. It is a recognition of this wide and essentially unpenetrated frontier, beyond which lie solutions to so many of the basic problems of biology, that gives to the study of development its challenging appeal.

EDMUND W. SINNOTT

THE MATHEMATICS OF EXPERIMENTATION

The Design and Analysis of Experiments

By Prof. Oscar Kempthorne. (Wiley Publications in Statistics.) Pp. xix+631. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1952.) 68s. net.

FOR all who design and analyse experiments, Cochran and Cox's "Experimental Designs" has rapidly become a standard work of reference. So extensive has the subject grown, however, that even this large volume, a manual of instruction with comparatively little explanation of principles, cannot deal adequately with confounded and incomplete block designs. Prof. O. Kempthorne's book attempts to fill this gap by presenting the general statistical theory on which all uses of experimental designs rest, together with instructions for constructing, analysing and interpreting some of the more complex designs.

The first two chapters contain a survey of the philosophy of scientific experiment that must surely be too brief for a newcomer to the subject, yet scarcely necessary for the more experienced. A short chapter outlining standard statistical procedures is followed by two important chapters on the theory of least squares, with particular reference to linear hypotheses; the emphasis throughout is on the Markoff approach. From this point onwards, the book is more directly concerned with the structure of different types of design and with the calculation and interpretation of the corresponding analyses of variance. Randomized blocks, Latin squares, and other fully orthogonal systems of classifications are discussed, as are the modifications in analysis required when 'plots' are missing. Full presentation of factorial design, including confounding and fractional replication, occupies several chapters; these relate primarily to 2^n and 3^n arrangements, but the general p^n is included, as also are those with factors at different numbers of levels. Another series of chapters is concerned with lattices; the structure and general method of analysis is explained and related to factorial design, and formulæ appropriate to each type are displayed. This leads naturally to similar discussion of the non-lattice incomplete block designs, balanced and partially balanced. Finally, two short chapters are concerned with problems that arise in the analysis of groups of experiments and of experiments with several treatments applied in succession to the same 'plot'; the accounts given are less complete, but provide an interesting introduction to difficult matters.

The argument is set out mainly with reference to agricultural field trials; but its applicability is in no way restricted to these. The author shows how the mathematical model underlying observational data determines the form of the analysis of variance, and how knowledge of the expectations of mean squares is essential to the interpretation of the analysis; he presents several illustrations of the way in which naïve comparisons of mean squares can mislead. In early chapters, he appears to insist that only randomization tests of significance are legitimate, though he never explains why the assumption of a normal distribution for the error in an additive model should be so objectionable; in much of the later part of the book this principle seems to be conveniently forgotten. "It is, perhaps, unnecessary to state that, if a transformation is used, the best estimates of the treatment means on the untransformed scale are obtained by transforming back the means of the transformed variate"—'untrue' would be preferable to 'unnecessary'. Such errors are happily rare; but the writing is not always clear, and the index is unworthy of so ambitious a book.

This book will unquestionably be valuable to statisticians, yet perhaps its value lies in the details of methods that it contains rather than in the whole view of experimental design that it presents. For routine computation, special formulæ for each design are a convenience; provided that the principles governing their derivation are understood, they are of little interest to the reader of a book which seeks to explain the theory of design and may obscure the unity of the subject. Possibly Prof. Kempthorne has attempted too much, even for a large volume. The great need to-day is for a book that displays the fundamental ideas of experimental design and analysis fully and systematically for the serious student while retaining the comprehensive outlook of Fisher's "The Design of Experiments"; "The Design and Analysis of Experiments" tries to combine with this a manual of detailed instructions for analysis and, in so doing, fails to attain the highest level for either. Prof. Kempthorne is to be congratulated on so nearly succeeding in a difficult task; the ideal book has yet to be written, and ought to make experimental design appear an easier subject than does this one.

D. J. FINNEY

PHILOSOPHICAL AND BIOGRAPHICAL ESSAYS

Ethics and the History of Philosophy

Selected Essays. By Prof. C. D. Broad. (International Library of Psychology, Philosophy and Scientific Method.) Pp. xiii+274. (London: Routledge and Kegan Paul, Ltd., 1952.) 21*s*. net.

PROF. C. D. BROAD here reprints selections from articles and public lectures produced between 1925 and 1949. They are very welcome. The first, biographical, section of the book contains essays on Isaac Newton, John Locke, Henry Sidgwick, J. M. E. McTaggart and W. E. Johnson. The first two celebrate centenaries of famous men, and fulfil their function gracefully. The last two are useful reminders of thinkers recently dead, who were never fashionable and are never likely to be. Yet, when all the more fashionable philosophers are forgotten, they may be remembered—McTaggart for penetrating criticism and daring attempts in philosophical method, and Johnson for fertile conceptions not yet fully developed. Prof. Broad knew them personally and gives a pleasing sketch of their characters as well as a useful brief account of their work. Sidgwick belonged to an earlier generation of Cambridge philosophers, one of the most distinguished, and yet he stands even more in need of commemoration.

The essay on "The Philosophy of Francis Bacon" is the most valuable feature of the section headed "Philosophy of Science". Bacon has been extravagantly praised and extravagantly defamed; very few have stopped to consider carefully what he had to say, and nobody has summed it up better than does Prof. Broad here. The second essay, called "The New Philosophy: Bruno to Descartes", is a clear straightforward account of the main features of Thomist cosmology and of what Descartes proposed to put in its place. Bruno does not come into the story except by being born in 1548, when cracks in the old cosmology were beginning to be visible. In the third essay, "Leibniz's Last Controversy with the Newtonians", Prof. Broad analyses the argument of his correspondence with Samuel Clarke, and gives also some interesting information about Clarke himself. This correspondence makes a difficult and disappointing book. Neither disputant seemed able to see what the other was trying to get at, and both acted in accordance with Disraeli's advice—"Never argue with an opponent; repeat your original statement". This advice is not as useful in philosophy as in politics. Many who have been baffled by the book will welcome Prof. Broad's account, and particularly his analysis of the rival theories of space and time.

The section headed "Ethics" begins with Prof. Broad's inaugural lecture as Knightsbridge professor in Cambridge. This must have made it clear to hesitant undergraduates that during his tenure of the chair the subject of moral philosophy would not be a soft option, but a strenuous intellectual exercise in the analysis of ethical concepts. All four constituents of this section are examples of this. The second one, on "Egoism as a Theory of Human Motives", shows that it is a far more difficult theory than simple-minded egoists suppose. The one entitled "Ought We to Fight for our Country in the Next War", besides its intrinsic interest, must have provided an effective douche of cold water for young intellectuals of the 1930's who were too clever and up to date to fight for anything but ideologies. The last essay, on "Conscience and Conscientious Action", is an admirable example of clarity and good sense on a theme where confusion and nonsense too often prevail, equally on the side of those who claim conscience as an infallible guide and those who claim that it is an illusion of the bourgeoisie.

TIME AND EVOLUTION

Time's Arrow and Evolution

By Harold F. Blum. Pp. xi+222+4 plates. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1951.) 25*s*. net.

DURING most of the period in which people have argued about things, the legal, medical and military importance of the distinction between a living and a dead animal or man was recognized; but no advantage was seen in erecting the metaphysical concept of the living or non-living state. During the seventeenth and eighteenth centuries a liking for the distinction developed and hardened into a complete dichotomy at the end of the last century. The hardening is often attributed to Pasteur, but this is unfair to him; he demolished with humour and emphasis all the claims made for "spontaneous generation" but still said he thought it could happen. This attitude of believing in a possibility while disbelieving in alleged examples of it permeated the writings of Huxley and Tyndall and has now become common among biologists.

The older writers realized that they knew too little about the primitive state of the earth to make speculation on the origin of life profitable; but as knowledge increases the temptation to speculate increases too, and we now have a steady stream of books on the subject. Dr. H. F. Blum has written one of the better books in this category. He surveys cosmogony, geochemistry, thermodynamics and biochemistry briefly but in a manner adequate for his purpose. He then sensibly points out that primitive forms of life might well pass unrecognized if present-day standards are used, and that a point of origin could arbitrarily be placed almost anywhere along a thousand million-year stretch in the Pre-Cambrian. Making use of this permitted arbitrariness, he chooses as the origin of life the time when proteins first appeared; but he does not explain how, rigidly, he would define a protein. This is the main weakness of the book, for there is no reason for assuming that proteins are the basis of the only possible mode of existence of organisms on the earth. It is obvious that they play a basic part in the most successful way of living, and it is probable that they have done this throughout the five hundred million years of morphological evolution which is the only period about which we have any evidence. But it is a pure assumption that this was also so during the earlier millennia of biochemical evolution. We have so often been led into error by assuming that biology is simple that we should be wary of all unjustified, and it may be said unnecessary, assumptions.

This book achieves what it sets out to achieve. It is popular, written in a popular manner and embellished with some very popular analogies. The author only claims originality for the idea that in the pre-vital phase of the earth's history the adenosine triphosphate cycle evolved and that it engineered the synthesis of primitive nucleoproteins. This is a distinction that few will grudge him. Nevertheless, much of the argument is presented as if it were novel, and many readers may not realize that all the significant parts appeared long ago in the writings of Huxley, Tyndall and Schafer, for these are neither quoted nor mentioned in the book.

N. W. Pirie

AFRICANA UPSALIENSIA

Contribution to the Ethnography of Africa

By Sture Lagercrantz. (Studia Ethnographica Upsaliensia, 1.) Pp. xix+430. £9.

Origin of Death

Studies in African Mythology. By Hans Abrahamsson. (Studia Ethnographica Upsaliensia, 3.) Pp. vii+178. £3.

(Uppsala: Almquist and Wiksell; London: Routledge and Kegan Paul, Ltd., 1950–51.)

We are indebted to the Humanistic Foundation of Sweden for the publication of a series of six anthropological studies dealing with the comparative ethnology of Africa. The two which are reviewed here, "Contribution to the Ethnography of Africa" and the "Origin of Death", are weighty and erudite studies of the diffusion of culture in Africa. The aim of the two authors, who follow the Continental diffusionist school of Graebner and Schmidt, is to test the theories of this school regarding the successive cultures of Africa by a comprehensive examination of all the literature that has been published on African anthropology since the theories were first propounded. S. Lagercrantz, the general editor of the series, does this, in the first and largest volume, by examining particular culture traits grouped under the general headings of food, ornaments, weapons, commerce, art, medicine, divine kingship and religion. Abrahamsson, in the "Origin of Death", which is actually the third volume in the series, makes a similar examination of particular themes of African folk-lore which seek to explain how death came to the world.

Lagercrantz, in his introduction to the first volume, briefly surveys the successive culture theories held by the leaders of this school, ending with those of Baumann, who in 1940 distinguished seven hypothetical cultures—pygmy, Eurafrican steppe, old African (Ankermann's old Sudanese), west African, east Hamitic, north Hamitic and a young Sudanese—which last is also claimed to have a counterpart in the Zimbabwe culture of Rhodesia. Lagercrantz's conclusion is that Baumann "may probably be said to have resolved some of the most important problems of African research in a way that on the whole is likely to prove of permanent value". It is very doubtful if this opinion would be shared by most British or American Africanists, but their aims and methods are entirely different. British social anthropologists are concerned with the study of contemporary African societies as they exist at present or in the historic past. The Uppsala ethnologists are concerned with the interpretation of contemporary African cultures in terms of their origins, and their endeavour is to deduce these origins from a study of the distribution of isolated culture traits which are regarded as the survivals of these earlier hypothetical cultures.

Readers who are interested in the diffusion of particular culture traits will find in these volumes, particularly the first, a mass of interesting material; those who wish to study contemporary African societies will merely be irritated by them; and the scientifically minded will note the absence of any first-hand archæological or anthropological field-work and will wonder whether this technique of culture analysis, useful as it may be in the case of European ethnography where it can fall back on corroborative archæological and historical research, can validly be applied to a continent so deficient in such research.

G. I. Jones

FRONTIERS OF ORGANIC CHEMISTRY

Progress in Organic Chemistry, 1

Editor: Prof. J. W. Cook. (Progress Series.) Pp. viii+287. (London: Butterworths Scientific Publications, Ltd., 1952.) 50s. net.

A glance at the current journals of the chemical societies of the world will show that organic chemistry remains an immensely fruitful and popular branch of science. A correspondingly heavy burden is placed on organic chemists and others concerned in keeping afloat in the cataract of literature. Fortunately the position is relieved by the increasing tendency to publish reviews of comparatively small sections of the subject. Among such reviews the collection of monographs entitled "Progress in Organic Chemistry, 1" is among the most authoritative.

Eight articles are included, all written by active workers in the different fields. To attempt a brief classification: four deal with natural products (Sir Robert Robinson on strychnine; H. Erdtman on heart-wood constituents; H. H. Brockmann on photodynamic pigments; I. A. Preece on starch); two deal with general synthetic and industrial organic chemistry (S. F. Birch on petroleum chemicals; B. C. L. Weedon on acetylene chemistry); one deals with reaction mechanisms (D. H. Hey on free radicals as intermediates); and one with chemotherapy (F. Bergel and A. S. Parkes on drugs inhibiting symptomatic stimulators). As might be expected from this list of authors, the general level of the contributions is remarkably high. It is of particular value to have from the highest authority a logical summary of the elucidation of the tangled structure of strychnine, coming as it does immediately after the final solution. Among the other monographs one notes particularly those of Erdtman and of Brockmann as authoritative reviews of most interesting groups of compounds. Bergel and Parkes's article is remarkable for its range, and Birch's for its timeliness.

A readable book of less than three hundred pages dealing with progress in organic chemistry can only touch on a few topics, and Prof. J. W. Cook has done well to limit these so that the treatment may be thorough. Nevertheless the book as a whole suffers from the defects of its qualities: it admirably describes *examples* of progress rather than the progress as a whole. It is probably true that the subject is now so wide that it can only be reasonably covered by a number of volumes like this, each dealing with one important aspect, such as natural products, synthetic methods, reaction mechanisms and so on.

The book is well printed and free from errors.

R. P. Linstead

IONIZATION, pH AND BIOLOGICAL ACTIVITY*

BIOLOGICAL activity is known to be influenced by many physical and chemical factors; of these the degree of ionization is recognized as outstandingly significant. A change in biological response has often been observed to accompany a change in the degree of ionization of a drug, or of its biological receptor. Many common drugs, and other biologically active substances, are capable of undergoing this change in ionization somewhere within the physiologically interesting pH range. This would not be significant if both the molecule and the ion had the same biological action; however, in all cases that have been investigated, ions and the corresponding neutral molecules have been found to behave differently.

Chemistry of Ionization

With few exceptions, salts are completely ionized when in solution, and thus they can have no biological properties other than those of the individual ions of which they are composed. This simple conception is not always recognized by biological workers.

Unlike salts, acids and bases need not be completely ionized in solution. Strong acids and strong bases (for example, sodium hydroxide and hydrochloric acid) are completely ionized in the pH range of 0–14, but many biologically active substances are weak acids or bases and thus show variable ionization within this pH range. The degree of ionization in solution depends on only two factors, the pH and the pK_a. The latter is a constant for any acid or base, and thus, if the pH is controlled, the degree of ionization depends only on the nature of the acid (or base) being investigated.

By application of the law of mass action to the ionization of weak acids we obtain a quantity known as the acidic ionization constant (K_a), sometimes, but not so correctly, called the 'dissociation constant'. The degree of ionization of weak bases also can be described by acidic ionization constants. These ionization constants are small and inconvenient figures, and it is usual to employ their negative logarithms which are known as pK_a values. Thus, pK_a values provide a convenient way of comparing the strengths of acids (and of bases): strong acids have low pK_a values, strong bases have high ones.

An acid or base when half-ionized has a pH equal to its pK_a. On passing from a pH value which is one unit on one side of the pK_a to a pH value one unit on the other side, a given drug is converted from a substantially ionized to a substantially non-ionized condition. Hence, quite small changes in the pH of a solution can produce large alterations in the degree of ionization of a drug, and this may well result in a modified biological effect.

Influence of Ionization on Biological Action

The organic chemist frequently finds that chemical reactivity depends upon the degree of ionization. For example, dimethylaniline normally nitrates in the *ortho* and *para* positions; but if sufficient concentrated sulphuric acid is present for the substance to be entirely converted to the cation, the nitration occurs exclusively in the *meta* position. Similarly, the degree of ionization can influence biological action.

The ready reversibility of drug action by dialysis indicates that the drug and receptor appear to be held together by readily breakable bonds (for example, ionic bonds but not covalent bonds). Hence changes in the pH of the medium bathing a receptor, or use of an analogue of the drug with a different pK_a, might be expected to bring about a change in biological response in many cases.

Adsorption at surfaces is a second method by which ionization can affect biological action. Ionization is usually unfavourable to non-specific adsorption, where the neutral molecule is adsorbed and the more highly hydrated ion tends to remain in the water. On the other hand, specific adsorption, which depends upon the drug being complementary in shape or charge to the receptor, may favour preferential adsorption of the ion.

The degree of ionization can also influence greatly the ability of a drug to penetrate natural membranes. In general, the ionic form of a substance penetrates membranes much more slowly than the neutral molecule, as the ionic group is held by unlike charges on the outer surface of the membrane and repelled by like charges. However, certain ions, such as those of sodium and chlorine, appear to penetrate by special mechanisms, and the penetration of ionic drugs can often be assisted by the addition of lipophilic substituents such as chlorine or alkyl side-chains.

The action of a drug obviously depends not only upon its ability to combine with some vitally important substance in a certain tissue, but also upon the ability of the drug to reach that tissue. Many important drugs have a pK_a between 6 and 8, and this means that, at the physiologically important pH of 7, the drug is always in equilibrium with at least 10 per cent of its ionic form. Such drugs can pass through a membrane which would exclude ions, and yet they can regenerate some ions (by mass action) on the far side of the membrane.

It was once thought that the degree of ionization could not be of great importance in biology. It was considered that, as the biological receptors removed the toxic ionic species, more would be generated in accord with the law of mass action. However, many cases are now known where biological activity is highly dependent upon the degree of ionization. This indicates that the combination between drug and receptor is usually weak and completely reversible in nature. In a system in which a biological receptor is in equilibrium with a low concentration of a toxic ion and a high concentration of the corresponding molecule, a stability constant (K_s) can be assigned to the drug-receptor complex:

$$K_s = \frac{[\text{drug-receptor complex}]}{[\text{toxic ion}]\,[\text{receptor}]}.$$

Thus the concentration of toxic ion in solution is controlled by this relationship, and it is also controlled by the ionization constant (K_a) of the drug. Where K_s and K_a are of similar magnitude, it is obvious that any deficiency of toxic ions in the solution will be replenished from the drug-receptor complex as easily as from the non-ionized drug. Under these conditions, the degree of ionization of the drug governs its efficiency; the greater the number of ions present, the greater will be the number forced into the drug-receptor complex. It must also be noted that the toxic ion may combine with non-vital groups, and this can lead to wastage of large quantities of the toxic agent.

---

* Substance of three University lectures by Prof. Adrien Albert, delivered at University College, London, on October 13, 20 and 27.

The acridine antibacterials provide the best-known example of a positive correlation between ionization and biological activity. For example, only five different mono-aminoacridines can exist. Of these, two are highly ionized at pH 7 (5-amino- and 2-amino-), whereas the other three ionize to only a small extent. The two isomers which are well ionized have a powerful antibacterial action, whereas the three isomers which are poorly ionized have only a feeble action. The same correlation has been demonstrated in more than one hundred acridines, and, provided that the ionization is cationic and is not less than 50 per cent at pH 7·3, the chemical nature of the substituents in the acridine nucleus makes little difference. By examination of the effect of these antibacterial acridines over an extended pH range, a direct competition between acridine cations and hydrogen ions has been revealed. The simplest interpretation of this interesting fact is that some vital anionic group in the bacterium is blocked by combination with the acridine cation and is thereby prevented from discharging its normal metabolic function.

In certain cases, however, ionization appears to be disadvantageous to biological activity. For example, the action of salicylic acid, which inhibits cell-division in echinoderm eggs, has been shown to be strictly proportional to the neutral molecules present. Between these two extremes we also find a number of cases of biological action in which the molecule is more active than the ion, but in which the ion does show some activity.

Not only is the ionization of the drug important, but also the ionization of receptors. A biological receptor is regarded as a molecule, or portion of a molecule, the normal function of which in metabolism can be blocked by combination with an appropriate drug. There is evidence that receptors are often co-enzymes or the protein component of enzyme systems. The receptors which are relevant to the present discussion are those which can combine with drugs by ionic bonds, and which only ionizable drugs can block. The pK_a values of receptors cannot be predicted in advance of experiment, as their chemical nature is largely unknown.

Not all receptors are actually within the cell. For example, amœbæ are narcotized when undecane is injected into the external membrane, but not when it is injected into the amœba. The pK_a of a receptor which is on the outside of a cell can be studied by the response to drugs over a range of pH values, provided that the cell is otherwise unaffected by the pH range and that the ionization of the drug does not change within the range. It is known, for example, that the receptors for cationic antibacterials are on the outside of cells because the addition of lipophilic groups to the molecule does not increase the efficiency of the drug. Further, derivatives which yield 70 per cent of cation at pH 7 are no more active than those which yield almost 100 per cent. The point which must be borne in mind is that the receptor may be expected to change its degree of ionization as the pH is changed.

Ionization studies become more difficult when the receptor is within the cell. Very little is known of the pH within animal cells, and the results obtained from experiments with indicators must be treated with reserve. By an enzyme-activity method it has been shown that the pH within the cell, in at least one case, roughly corresponds to that of the buffer in which it is placed.

Thus it is desirable, in biological experiments, to work in buffer, which ensures that the drug is presented to the cell in a standard state of ionization, and also maintains, in a standard state, the mechanisms for the adsorption of the drug and its penetration into the cell.

Further Aspects of the Chemistry of Ionization

Many ionization constants vary with temperature. This effect is most marked with strong bases, which become much weaker as the temperature rises. Mention must also be made of zwitterions, that is, ionic forms which carry both positive and negative charges. Zwitterions are usually rather inert biologically; for example, histidine has none of the marked physiological properties shown by the corresponding cation, histamine.

A small potential has been found to exist between biological surfaces and water. This is the electrokinetic, or zeta, potential, and its existence has been held to imply that there must be a slight difference between the pH at the surface and the pH of the solution.

It has been found that some few cations are capable of combining with hydroxyl ions by means of covalent bonds to give non-ionized substances known as 'pseudo-bases', from which the original cation can be regenerated by acid. This reaction, unlike normal ionic equilibria, is rather slow, and it may require from an hour to a week for equilibrium to be achieved. It is impossible for the biologist to correlate ionization with biological response if pseudo-bases are involved, unless he has first ascertained the pK_a at equilibrium and the time taken to achieve equilibrium. The most common examples of pseudo-base formation are furnished by heterocyclic quaternary compounds and by triphenylmethane dyes.

A further example of ionization which must be considered is due to the thermodynamic activity effect. When anions and cations are present in concentrated solution, they tend to form ion-pairs and thus behave as though a small fraction of their total concentration were absent. This effect is reflected in pK_a values, both acids and bases appearing slightly weaker in strong solutions. Ions of formula weight more than two hundred have a greater tendency to form ion-pairs than simple ions and thus show considerably greater activity effects, that is, the proportion of free to bound ions becomes very low. Drugs which are desired to provide a depot effect, for example, globin-insulin and procaine penicillin, can be formed by combining a therapeutically active ion with an oppositely charged ion, both being of fairly high molecular weight. Such compounds are slow to release curative ions because of their large thermodynamic activity effect.

Organic molecules having two neighbouring groups, one an anion and the other an electron donor such as a nitrogen or oxygen atom, can form chelate compounds with metallic ions. These are essentially salts the activity of which is maintained far below their concentration, and metallic complexes of this type play an enormous part in biochemical processes.

It will be apparent from this discussion that knowledge of the ionization constants of biologically important substances is of great importance to the biologist. This information allows one of the most common variables to be brought under control and thus can add greatly to the scientific knowledge derivable from a biological experiment.

H. C. S. Wood

COMPARATIVE PHYSIOLOGY OF MUSCLE

On September 5 at the British Association meeting in Belfast, Sections D (Zoology) and I (Physiology) held a joint half-day session on the comparative physiology of muscles, under the chairmanship of Prof. R. C. Garry, president of Section I. The meeting was well attended, and it admirably fulfilled the two purposes of presenting part of an important modern field of research to non-specialists, and of providing a meeting ground for research workers concerned with different aspects of the behaviour of muscles. At the end of the morning, Prof. Garry commented on the success of the discussion, saying that this joint meeting of the two Sections had shown the importance of research into comparative muscle physiology, and the importance of considering structural changes at the same time as investigating the more physiological aspects of muscular contraction.

The discussion was introduced by Prof. A. V. Hill, who briefly reviewed the features that appear to be common to all contractile tissues, and their specializations for different purposes. He then directed attention to the important results, now published[1], which Dr. T. Weis-Fogh has recently obtained on the metabolism of flying locusts. Measurements of the amounts of fat and glycogen in the body before and after tethered flight indicate that migrating locusts (*Schistocerca gregaria* Forskål) are mainly dependent on fats for the fuel to sustain long periods of flight. Thus their flight muscles appear to be atypical: carbohydrates are generally considered to be the fuel used by most muscles. Locusts probably deplete most of their reserves of muscle glycogen during the 'warming up' activity preceding each day's flight; and when migration begins, they have mobilized other fuel reserves held elsewhere in the body, especially the fat in the fat bodies. Dr. Weis-Fogh has pointed out that the hydration of stored glycogen makes it about eight times heavier than isocaloric quantities of fat. Fats are thus very suitable food reserves for animals that fly for long periods, provided that they can be mobilized, and provided that the muscles have an adequate supply of oxygen. It is calculated that migrating locusts must eat at least one and a half times their own weight of food each day. A large swarm, weighing 13,000–19,000 tons, uses 500–800 tons of fat for its daily flight, and needs to consume a quantity of food that would supply one and a half million human beings with the calories they need each day. The metabolic rate of the flight muscles of locusts is very much higher than that of other striated muscles: for example, 400–800 kcal./kgm./hr. for locusts, as compared with 50–60 kcal./kgm./hr. for human leg muscles. Flies and bees and other insects have even higher metabolic rates, but their muscles use carbohydrates. It appears that many other muscles, not only those of locusts, are able to use fats as well as carbohydrates, but this faculty is especially highly developed in locusts. These specializations in muscle metabolism may ultimately be dependent on specializations in the enzyme systems of the muscle mitochondria.

Mr. J. Lowy (Laboratory of the Marine Biological Association, Plymouth) presented the results of his work on the smooth muscles of bivalve molluscs, particularly of the mussel *Mytilus edulis*. These animals, in their natural environment, are exposed to the air for long periods when the tide is low, and although the elastic ligament at the hinge of the shell tends to make the two valves gape apart, closure is maintained by the adductor muscles. Mr. Lowy's work has indicated that the adductor muscles can maintain a state of active contraction throughout long periods, and that it is probably unnecessary to postulate a special 'catch mechanism' in these muscles to account for their ability to maintain prolonged closure of the shell. Simultaneous recordings were made of shell movements and of the electrical activity in the posterior adductor muscle, both when the animals were exposed to the air (shells closed) and when they were in sea water (shells opening and closing at irregular intervals). Records of action potentials, some of them as large as 100 μV., were obtained not only when the muscles were contracting to close a gaping shell, but also throughout long periods of as much as two hundred hours when the shell was kept closed and the animal out of water. That the records of electrical activity pertain to the muscles and not to the nerves is suggested by the results of experiments on nerve-muscle preparations made from the pedal retractor muscle and pedal nerve of *Mytilus* and the anterior adductor muscle and its motor nerve in *Mya arenaria*: the electrical activity recorded from these muscle preparations when they were indirectly stimulated was similar to that recorded from these muscles or from the posterior adductor muscle of *Mytilus* during spontaneous activity, and it was dissimilar to that recorded from the nerves. It was also shown that there are no intramuscular nerve cells. It therefore seems to be clear that both intermittent and prolonged closure of the shell is brought about by typical contractions of the adductor muscle fibres.

Mr. Lowy has also found that electrical activity in the posterior adductor muscle ceases when the visceral ganglia are extirpated, although it continues if the visceral ganglia remain in place but the pallial nerves and the cerebro-visceral connectives are cut. These experiments suggest that nerve elements in the visceral ganglia are responsible for maintaining contraction of the posterior adductor muscle, and other experiments suggest that the visceral ganglia are also concerned in the initiation of relaxation. Relaxation could be brought about by appropriate tactile stimulation of the visceral ganglia, or of the mantle edge or cerebral ganglia. In some cases relaxation was accompanied by electrical activity in the adductor muscles, but in other cases electrical activity was suppressed while the muscles were relaxing.

The neuro-muscular mechanism of the insect leg was the subject discussed by Dr. G. M. Hughes (Department of Zoology, Cambridge). Most of his observations have been made on cockroaches. Analysis of cinematographic records of walking and running cockroaches shows that these insects modify their gait according to their speed; but both speed and gait change gradually, and there is no sharply defined change-over from walking rhythm to running rhythm. Records of the electrical and contractile activity in isolated preparations of the flexor muscle of the tibia have led to the conclusion that the individual muscle fibres have a multiple innervation and can contract at different speeds. There are at least three different patterns of action potential records, correlated with different speeds of contraction. It is suggested that changes in the number or type of nerves involved in stimulating the muscle fibres can produce changes in the speed of contraction of the fibres, and thus bring about the graded changes in the speed and gait of the whole insect.

Much can be learned about the performance of a muscle by finding what force it can exert in contraction, and by analysing the relationship between the force exerted and the velocity of shortening. The equation relating force to velocity is

$$(P + a)\,(V + b) = \text{constant} = (P_0 + a)b,$$

where P is force, V is velocity, a and b are constants, and P_0 is the force exerted under isometric conditions, that is, where velocity is zero. A. V. Hill has shown that this equation not only fits the force–velocity curve but also expresses the way in which heat is emitted during contraction. It is therefore important to find how far different kinds of muscles and the muscles of different animals have mechanical properties which can be expressed by this equation. B. C. Abbott and D. R. Wilkie (Departments of Biophysics and Physiology, University College, London) have studied this question. Their experiments were made on isolated muscles from snails, dogfishes, rays, tortoises, frogs and toads, and results have also been obtained for human muscles by experiments on intact subjects. In all these muscles the tension developed during isometric contraction depends on the length at which the muscle is held, being greatest at about the length the muscle has in the body. During isotonic contraction, the greater the weight that the muscle has to lift the smaller is the amount of shortening. The velocity of shortening is greatest when the weight is least, and the equation relating force to velocity is the same for all the muscles investigated. The most striking difference found was in the maximal velocity the muscle could attain: this varied over a sixty-fold range from snail to man.

In the last paper, Dr. E. Jean Hanson (Medical Research Council Biophysics Research Unit, King's College, London) dealt with two aspects of muscle cytology relevant to comparative studies of muscle physiology. The cross-striations of isolated vertebrate and insect myofibrils have been studied in positive phase-contrast illumination, in polarized light and in the electron microscope. Isolated fibrils have been induced to contract by treatment with adenosine triphosphate, and the process of contraction has been watched in the microscope and the changes in the pattern of cross-striations studied. The conclusion has been reached that a material, provisionally called the 'A substance', which is segregated in the isotropic bands of relaxed fibrils, migrates during contraction along the long axis of the fibril, and most of it comes to lie in a set of new bands, the contraction bands, at the end of contraction. In spite of this change in the distribution of materials, the alternation of anisotropic and isotropic bands along the length of the fibril remains unchanged, and the factors responsible for birefringence are unknown.[1] Contraction of myofibrils induced by adenosine triphosphate is irreversible, but there is reason to suppose that in other respects it is similar to normal contraction and that a migration of the unknown 'A substance' takes place when a muscle contracts ***in vivo***. Finally, some observations on the smooth muscles of molluscs and annelids were briefly reported; the muscles investigated included those discussed earlier in this meeting by Lowy, Abbott and Wilkie. Fibres of these invertebrate smooth muscles, unlike the fibres of striped muscles, contain large quantities of proteins of the paramyosin type, about which little is yet known. Whereas a striped muscle fibre consists predominantly of actin and myosin, the two structural proteins concerned in contraction, molluscan and annelid smooth muscles have complex fibres consisting both of contractile myofibrils and of bundles of paramyosin or related fibrils. These bundles are responsible for the characteristic double oblique striation of these fibres. Paramyosin is very unlikely to be contractile, and it may be mainly responsible for many of the peculiar properties of these smooth muscles, for example, their extensibility and 'viscosity'.

CLASSIFICATION OF THE FUNGI

LIEUT.-COLONEL R. B. SEYMOUR SEWELL took the chair at the meeting of the Linnean Society on October 23, when a discussion was held on the "Classification of the Fungi".

Dr. B. Barnes said that the lower fungi, or Phycomycetes, are a heterogeneous group, separated from the other fungi by the usually cœnocytic vegetative body. This may be a rounded or lobed sac, a branched structure of characteristic shape, or, in the higher forms, a spreading mycelium. Septation in the vegetative body usually accompanies the formation of reproductive organs. In origin, septation may have been associated with the production of reproductive structures carried above the bacterial slime on the submerged substrata inhabited by many of these fungi. It seems likely that, during the course of evolution, septum formation has moved backwards in ontogeny; in some existing species, septate vegetative bodies occur in juvenile specimens. The septate vegetative body may well be in a physiological condition intermediate between that of the vegetative state and of the reproductive state.

Phycomycetes show some peculiar features distributed rather haphazardly among the members of the group, features scarcely of adaptive significance and more probably inheritances from the remote past. Notable among these features are: the persistent empty wall of the zoospore, the occurrence of two phases of motility with differences in morphology of the zoospore (diplanetism), and the assumption of amœboid characters by the zoospore. These features occur chiefly in a number of the Chytridiales and the Saprolegniales. From these two stocks, rather vague connexions may be traced to the other alliances of the Phycomycetes.

The Monadineæ Zoosporeæ occur as parasites or as saprophytes in algæ, fungi and bryophytes, and probably as common saprophytes in the soil. They are very simple, and can scarcely be regarded as fungi, though in life-history and in organization they agree well with the simpler members of the Chytridiales and Saprolegniales. They differ in the tardy formation of a wall around the trophic body and in the ingestion of solid food with the ejection of solid residues of digestion. In the Monadineæ Zoosporeæ and in the Phycomycetes, series may be traced, characterized by uniflagellate, biflagellate and non-flagellate spores: this appears very significant. Some of the Monadineæ Zoosporeæ leave persistent empty zoospore walls, and some show signs of diplanetism; amœboid stages are common. These points also are significant. Many members of the group are very common and they deserve more study than they have yet had. If this shows that features of life-history and behaviour are common to some of the simplest organisms yet known, and to the Phycomycetes, it must follow that the fungi are not plants, but lie on lines of development separate from those which run through the animals and the green plants. It must follow that the fungi are not decolorized algæ. Such research must be directed to the tracing of tendencies, and not to an effort to show that an existing species or genus is ancestral to, or derived from, another existing species or genus.

Dr. E. J. H. Corner pointed out that the purpose of classification is the identification of organisms and the recognition of their positions in an evolutionary system. Artificial systems frustrate research. Classification is concerned with genera, tribes and families. Speculation about phylogeny is an essential part of the work, for speculation is the ignition of taxonomy.

The classification of the higher Basidiomycetes is very backward. It is too artificial to stimulate research, and too inaccurate to permit the reliable identification of the organisms. The physiology, genetics and ecology of the higher fungi must be brought into the account, for these are living topics.

The higher fungi have a mycelium and a fructification. The mycelium is too generalized to be of use in classification; it is very uniform, and doubtless very efficient. The fructification must be used. What is a mushroom? It is a precise device for the production and liberation of spores. The gills are put out of action when they are immersed in water, and the basidia collapse; therefore, drawings of basidia are usually artificial. The mushroom is an umbrella which protects the gills from rain but maintains humidity around the spores; the polypore is a bracket which acts similarly. In contrast, the discomycetous apothecium is a cup which holds water.

Clavaria has no protection for its spores, and shows the primitive arrangement. A survey of the world flora of clavarioid fungi shows that they contain at least six natural series of genera or groups of genera. The Clavariaceæ, as currently understood, is therefore an artificial assemblage. There is a set of tropical Clavariaceæ which shows a general agreement with the polypores. A great group of species, with yellow-brown fruit bodies, cuts right across the accepted lines of classification, and contains clavarioid, stereoid and hydnoid forms. In some members of this group, the hyphal walls thicken early. This hinders growth, and would prevent the development of a fructification of mushroom type, for that depends on thin-walled hyphæ.

The genera of the higher fungi need to be dissected out into phylogenetic units. For example, *Fomes applanatus*, *F. igniarius* and *F. fomentarius* look much alike; but microscopic analysis shows them to be very different. Use of the method of hyphal analysis will reveal many other examples, and may yield good evidence of relationships.

If *Clavaria* is primitive, the ends of the lines of development in the Gasteromycetes are doubtless mixed groups. It seems certain that the resupinate Thelephoraceæ are to be derived along a number of lines of development within the Hymenomycetes; even *Pterula* may have resupinate fructifications.

Dr. J. Ramsbottom said that the objects of classification are the identification of organisms and their arrangement in a scheme showing relationships; differences in physiology and in chemistry must be taken into account. Schemes of classification based on presumed affinities may be valuable aids to identification, just as are artificial keys, though these can be deceptive because they often give meagre details. In large herbaria, an artificial scheme can be justified on grounds of convenience; even an alphabetical arrangement can be defended.

Morphological characters may be of little use, as in the yeasts, where it has been necessary to use the methods developed by the bacteriologists in classification.

Fungal cultures often produce saltations, mutations and strains, and these new forms may remain constant in subsequent cultures. Parasitic fungi, such as the rusts, have biological races, which may arise by mutation or by natural hybridization. Some of the biological races of *Puccinia graminis* are very virulent. Natural or induced variation has been of great importance in the production of penicillin. After the Americans had found that *Penicillium notatum* would not grow in submerged culture, they found a good strain on a rotting melon, and improved it by treatment with X-rays and other means. These strains and biological races cannot be neglected by the taxonomist, if only because of their economic significance. Experience gained during the search for antibiotics has shown that the fungi cannot be classified on their products; mycology and biochemistry are not synonymous.

Attempts have been made to identify toadstools by the use of sulphovanillin and other chemicals; but such tests have not been used with discrimination. Nothing seems to be known of the results of applying these chemicals to the same species at different stages in development. The tests are crude, and they are not critical.

Little is known of natural variation in the fungi. *Laccaria laccata* is well known to vary greatly; but is it variable because it is common, or common because it is variable? *Armillaria mellea* is variable; but little has yet been done on its systematics. It has forms with and without rings. In the old classification, the ring was held to be of great importance, and it is still held in respect. The old classification of the agarics was based on spore colour and on gross morphology. It is quite artificial, but we must continue to use it, for there is nothing to replace it. The logical method would be to associate all species with comparable developmental histories, no matter what the spore colour or the arrangement of the gills. Spore-sculpture needs much more study, as has been pointed out by some French workers.

Most of the phylogenetic schemes proposed for the higher fungi are of no importance; they may be described as "evolution in our time". Certainly, fungi are not decadent algæ.

Much more detailed knowledge is required before good theoretical schemes can be constructed. Even before the idea of evolution was accepted, mycologists had recognized circles of affinity within the fungi. Evolution cannot be both the key to the problem and also the lock. A study of phylogeny may indicate what forms are primitive, and these are probably the simplest. But the evolutionary history of the higher fungi is still a mystery. A study of fairy rings suggests that the mycelium is much more important in reproduction than is the spore, and yet we have elaborate and extremely fertile fruit bodies.

Microscopic characters are of great significance in dealing with species, and hyphæ, as in the strands of *Merulius lacrymans*, may show much diversity of structure; they may have taxonomic significance. Biological characters must not be stressed too much. For example, the predacious fungi show a general and similar pattern of behaviour, but the predacious habit is to be found among Phycomycetes, Basidiomycetes and Hyphomycetes. B BARNES

ASH AND CLINKER IN INDUSTRY

By T. F. HURLEY, O.B.E.

Fuel Research Station, London, S.E.10

DURING October 28–29, a conference described as "A Special Study of Clinker and Ash in Industry" was held by the Institute of Fuel at the Institution of Mechanical Engineers. Twelve papers were discussed which covered the origin and nature of the mineral matter in coal; its laboratory examination; the extent to which it is responsible for atmospheric pollution; the methods by which it can be removed either from the coal itself or from the products of combustion; and its effect upon the utilization of coal in various types of industrial plant. The papers had been published in advance in the *Journal of the Institute of Fuel*, and the Institute hopes to publish the text of the papers and discussions in the near future (£1 1*s*.).

In the field of utilization, small industrial boilers, gas producers, steel works plant, and, looking ahead, the industrial coal-fired gas turbine were considered, but most attention was devoted to the large water-tube boilers used by the British Electricity Authority, which is the largest single user of coal. This one organization now consumes 35 million tons of coal per annum, and as the average ash content of the rough slack supplied to it is about 15 per cent, it has to deal with about 5 million tons of ash per annum. Merely to handle this quantity of waste material is a formidable task, but during recent years the problems associated with ash and clinker have been further increased as a result of the present tendency to generate electricity in mammoth power stations employing very large and costly boilers working at extremely high temperatures and pressures. Among other consequences, the size of the stations requires more elaborate and expensive plant to avoid excessive atmospheric pollution in their vicinity, the higher temperatures in the boilers lead to a more objectionable type of deposit upon the heating surfaces, and to take one of a small number of very large boilers off the line for cleaning out of its turn affects materially both the output of the station and the cost of the electricity generated.

Taking industry as a whole, the importance of ash is steadily increasing as a result of changing mining conditions, which have led to more and more mineral matter being included in the coal brought to the surface. Various reasons were given at the Conference, the chief of which were, first, that the better seams have been worked out and those now being mined not only contain more ash but also include more dirt bands; and, secondly, increased mechanization causes more dirt to be mined and at the same time reduces the quantity which can be removed from the coal underground. Excluding free dirt, British coal seams still contain on the average only 5·5 per cent of ash and probably compare favourably in this respect with those of other major coal producing countries; but for the reasons given, run-of-mine coal now includes on the average about 15 per cent of free dirt. This represented about 33 million tons of the 'raised and weighed' output for 1950.

It is obvious that the cost of mining dirt and bringing it to the surface is comparable with that of winning coal; but no suggestion was made at the Conference that the quantity of dirt brought to the surface could, or should, be reduced. In fact, a future increase in the ash content of coal was accepted as natural and inevitable.

Ash costs just as much as coal to convey from the pit head to the point of utilization, and at each stage beyond that it is a costly nuisance. Again taking modern power station practice as an example ash costs more to pulverize than coal and it causes more wear in the machinery; it affects adversely the efficiency of combustion; it requires the size and therefore the capital cost of the boilers to be larger and at the same time it increases the difficulties of design and operation; it necessitates the provision of ash-handling equipment comparable in size and cost with the boilers themselves, some of it forms objectionable deposits which reduce both the efficiency and the availability of the boiler; it requires the installation of expensive dust collectors to minimize atmospheric pollution and, even when it has been collected, its disposal is a major difficulty.

Many, but not all, of these effects can be reduced materially by using known methods of cleaning the coal at the pit, but this involves a high cost in capital equipment, power and labour. So recently as 1950 the National Coal Board asked in its annual report whether "it may sometimes not be more economical to save some or all the cost of coal preparation at the price of reduced efficiency in the final stage of conversion". To this question the National Coal Board itself now appears to provide its own answer by stating that when all the cleaning plants ordered between vesting date and the end of 1951 are in operation, they will deal with about 42½ million tons of coal per annum. More than 100 million tons of coal are already cleaned mechanically each year

On the other hand, the Conference showed that there is considerable divergence of opinion with regard to the extent to which it is economical to wash coal instead of dealing with the ash during utilization. This lack of agreement may arise from the wide variations which occur in the chemical composition of the mineral matter in coal and in the manner in which it is associated with the coal substance. Both the ease with which coal can be cleaned and the influence exerted by a given quantity of ash upon different industrial processes are affected by these variations.

Most coal-cleaning processes are based upon the difference between the specific gravities of coal and dirt, and some are capable of making a close 'cut' at any predetermined density. When, therefore, the material to be cleaned consists partly of coal particles containing little dirt and partly of dirt particles containing little coal, it is easy to separate it into 'clean' coal and 'pure' dirt. On the other hand, when the coal substance is 'intergrown' with mineral matter, the yield consists of three fractions: relatively clean coal, middlings and dirt. The washery manager then has to balance the overall cost of cleaning against the requirements of his market and to decide what proportion of ash he should allow to appear in each fraction—a task requiring great skill and experience.

With these broad principles in mind, the general opinion of the Conference appeared to be that in present circumstances the more easily cleaned coals should be washed, and the dirty coals, middlings and even the refuse should be burned in the colliery boilers or in power stations erected in the vicinity. Plant is already being installed to burn what would formerly have been regarded as waste material.

The quantity of ash in the coal most easily supplied to a particular industrial plant may well determine the type of combustion appliance to be employed. Thus a chain-grate stoker would not usually be used with coal containing more than about 15 per cent of ash, whereas pulverized fuel containing more than 25 per cent of ash can be used in large boilers. On the other hand, it is very difficult to collect and dispose of the large quantity of fine ash made from pulverized fuel.

The composition of the ash has an equally important bearing upon the type of equipment to be used. Thus, boilers fired with pulverized fuel are usually immune from troublesome bonded deposits; but severe deposits frequently occur in boilers fired with mechanical stokers when the coal contains relatively small quantities of chlorine (more than 0·3 per cent), sulphur (more than 1·8 per cent) or phosphorus (more than 0·03 per cent).

In the same way, the amount of iron in the ash influences its tendency to fuse and form clinker or slag in the furnace. In most cases this is a source of trouble; but in some modern designs the ash is fused deliberately to enable it to be disposed of more easily.

For control purposes, it is obviously desirable to be able to predict the clinkering properties of an ash by a preliminary laboratory examination; but this is rendered difficult by the fact that when the mineral matter in coal is heated it changes its composition in a manner depending on the conditions of heating. In addition, the distribution of its constituents in a finely divided laboratory sample is different from that in the original lump coal. It is, therefore, impossible to devise one laboratory test for ash fusion temperature which would simulate all industrial conditions, and it is not surprising that varying opinions were expressed as to the practical value of ash-fusion temperatures determined by the standard method, which is necessarily empirical.

In spite of the variable nature of ash and its varying importance when coal is burned in industrial plant, it is clear that, if fuel is to be marketed on a national scale, a fair price can be assigned to any particular coal only after a quantitative allowance has been made for its ash content. Various methods of doing so were described, but every paper read could be used to illustrate the difficulty of devising a universal formula to meet all cases.

In general, the Conference showed that practical means have been found for dealing with the industrial problems associated with the presence of mineral matter in coal and that considerable knowledge is available concerning its nature and its behaviour in industrial plant. Nevertheless, the difficulties caused by it tend to increase, rather than to decrease, and there can be little doubt that they will continue to present major problems so long as coal is used as a fuel.

NEWS and VIEWS

Mineralogy at the British Museum (Natural History): Dr. W. Campbell Smith, C.B.E.

Dr. Walter Campbell Smith retired at the end of November from the post of keeper of minerals at the British Museum (Natural History) after forty-two years service. Joining the staff of the Department of Mineralogy in 1910, he became deputy keeper in 1931 and succeeded to the keepership in 1937. He was mainly instrumental in the expansion of the rock collections and in applying modern optical techniques to their identification and nomenclature. His well-known guide to the Museum's rock collections and his arrangement and labelling of them in the Mineral Gallery are models of clarity and accuracy, objectives no less difficult to achieve in petrology than in other sciences. Dr. Campbell Smith's numerous publications have included studies both in petrology and mineralogy, notably his pioneer investigations on hybridism in igneous rocks, his contributions on the petrology of rocks collected on famous expeditions such as the British Antarctic (*Terra Nova*) 1910, and his descriptions of new minerals from the manganese mine at Benallt, North Wales. He served as president of Section C (Geology) of the British Association in 1950, and on that occasion presented a survey of knowledge on the stony meteorites. During his keepership he was promoted to the post of deputy chief scientific officer (1948), and as deputy director of the Natural History Museum he found further scope for his interests in natural history. The knowledge that Dr. Campbell Smith will be able to continue his researches in his chosen field after his retirement will give much pleasure to his numerous colleagues and friends, both at home and abroad.

Dr. F. A. Bannister

Dr. Frederick Allan Bannister, who succeeded Dr. Campbell Smith on December 1, joined the British Museum (Natural History) staff on September 1, 1927, filling the vacancy caused by E. D. Mountain's appointment as lecturer at Grahamstown, South Africa. Dr. Bannister went from the Whitgift School, Croydon, to Clare College, Cambridge, in 1920. He won a Goldsmith Exhibition in 1921 and was placed in the first class in both parts of the Natural Sciences Tripos, studying physics under Rutherford and mineralogy under Hutchinson. After a year of research work under the direction of Sir Edward Appleton in the Cavendish Laboratory, Cambridge, he joined the Western Electric Co. in 1924, an experience which stood him in good stead in his later work. In 1928 he spent a short time studying the methods of X-ray investigation of crystal structure under Sir William Bragg at the Royal Institution. On his return to the British Museum, Dr. Bannister set up apparatus for this work and very soon established a highly efficient laboratory in a partitioned-off corner of one of the rooms in the Department. This laboratory has been very active in the X-ray study of minerals and has a very high reputation for thoroughly accurate work among mineralogists at home and abroad. His lectures given at the Royal School of Mines in 1935 will still be remembered by those who were privileged to attend them. Dr. Bannister was honorary secretary of the X-ray Analysis Group of the Institute of Physics during 1945–48, and he attended the first general assembly of the International Union of Crystallography at Harvard in 1948 and the second assembly held in Stockholm in 1951.

A. A. Michelson (1852–1931)

ALBERT ABRAHAM MICHELSON, who was born a century ago, on December 19, 1852, at Strelno, in Prussia, near the Polish frontier, was perhaps the greatest authority of modern times on optics, and one of the most ingenious and accurate workers in experimental science. His family emigrated to the United States when he was two years old, and at the age of twenty-one he graduated from the United States Naval Academy, Annapolis, where he served as instructor in physics and chemistry during 1875–79. After studying at Berlin, Heidelberg and Paris, he held various posts before his appointment in 1892 as head of the Department of Physics at the new University of Chicago. His chief abiding interest was light, particularly the accurate determination of its velocity, and the study of optical interference. One of his greatest accomplishments was the construction of the interferometer known by his name, and among the many uses to which he put this instrument the most important were the determination of the international metre in Paris, the measurement of the angular diameter of a star, and the attempt to detect the relative motion of the earth in the ether. The negative outcome of the last-named experiment, carried out in collaboration with E. W. Morley, gave birth to a new philosophy of physical science, which culminated in Einstein's theories of relativity. With the aid of his échelon spectroscope Michelson examined the fine structure of spectral lines. The first American scientific worker to win the Nobel Prize for Physics (1907), he was a foreign member of the Royal Society and recipient of its Rumford and Copley Medals, and served on a number of international committees. He was a fine violinist and painter, and held that art finds its highest expression in science. He died of a cerebral hæmorrhage at Pasadena, California, on May 9, 1931, in his seventy-ninth year.

Antoine Henri Becquerel (1852–1908)

BORN in Paris a century ago, on December 15, 1852, Antoine Henri Becquerel came of a family long distinguished in the world of physical science. Educated at the École Polytechnique, Paris, his early studies were concerned with the magnetic rotation of the polarization plane of light, the influence of earth magnetism on the atmosphere, and the absorption of light by crystals. In 1892 he was appointed professor of physics at the Musée d'Histoire Naturelle—a chair held before him by his father, Alexandre Edmond Becquerel (1878), and by his grandfather, Antoine César Becquerel (1837). Three years later he became professor of physics at the École Polytechnique. His greatest achievement was the result of a lucky accident, but at the same time it was the culmination of a long series of carefully planned experiments. In 1896 he found that photographic plates, protected against ordinary actinic radiations, were fogged by emanations from uranium ores. His paper entitled "Sur les radiations émises par phosphorescence" (*C.R. Acad. Sci. Paris*, 122, 420; 1896) ushered in the new era of radioactivity. Their discoverer in 1903 shared the Nobel Prize for Physics with Pierre and Marie Curie, who in 1898 had isolated radium from pitchblende. Becquerel received the Rumford Medal of the Royal Society in 1900 and was elected president and permanent secretary of the Paris Academy of Sciences in 1908, and in the same year was elected a foreign member of the Royal Society. He died in Brittany on August 25 of that year.

Weights and Measures in Great Britain

A QUESTION regarding the report of the Committee on Weights and Measures Legislation (see *Nature*, July 28, 1951, p. 142) having been asked in the House of Commons, a written reply by Mr. Peter Thorneycroft, President of the Board of Trade, was published on November 11. Mr. Thorneycroft states that the Government is in general agreement with the decisions of Sir Hartley Shawcross announced on May 10 last year, and action has already been started on those recommendations which do not involve legislation. Referring to the metric system, he remarks "The Government are not prepared to proceed with the recommendation for the eventual abandonment of the imperial for the metric system of weights and measures. Consultations with countries of the Commonwealth have, however, shown widespread support for the suggestion that a firm and legally defined relationship between the imperial pound and yard and the international metre and kilogramme should be established. On account of the wide variety of the recommendations and extensive nature of the consultations, the legislation will not be introduced for some time."

Higher Education in Central Africa

IN a written reply to a question in the House of Commons on November 26, the Secretary of State for the Colonies, Mr. Oliver Lyttelton, stated that the commission set up by the Governments of Northern and Southern Rhodesia and Nyasaland, in connexion with the establishment in Central Africa of a college for higher education for Africans, consists of Sir Alexander Carr-Saunders (chairman), Dr. A. Kerr, Dr. A. V. Hill and Prof. F. G. Young, with Mr. Walter Adams as secretary. The commission is now in Central Africa and its terms of reference include a review of the observations regarding the site of the college made by the committee appointed by the Central African Council, the making of recommendations regarding the site, type of courses to be provided and qualifications for admission, as well as on the type of buildings required. The commission is also to draw up a draft constitution for the college and to advise upon the form of 'special relationship with an established university and on the staff required and its recruitment.

Current Literature relating to Scientific Instruments

THE British Scientific Instrument Research Association has issued monthly since 1946 a *Bulletin*, which consists almost entirely of abstracts of any articles, papers, etc., connected with scientific instruments which appear in technical and scientific publications throughout the world. Of course, the abstracting service does not have a fixed and precisely defined subject-field, for the selection of material depends on, among other factors, the interests of the changing membership of the Association, the extent and availability of other sources of information, and the trends of interest revealed by inquiries made by staff who do the abstracting; consequently, a subject may be more fully covered during one period than in another. The *Bulletin* has grown with the years and has now achieved a reputation of filling a very real need and of doing so with considerable adequacy. Its functions are twofold, the first of which is to provide readers each month with a survey of current scientific publications on subjects of interest to them, and in this connexion it is best read like any other periodical review, that is, regularly and as soon after publication as possible. But it may not be realized in some quarters that, by virtue of its annual indexes, the *Bulletin* also serves as a permanent source of reference; indeed, the accumulated copies of the *Bulletin* and its indexes probably provide one of the easiest means of finding information which is related to scientific instruments and has been published within the past six years. All inquiries relating to these abstracts or to scientific instruments in general should be addressed to the Information Department, 'Sira', Southill, Elmstead Woods, Chislehurst, Kent (see also p. 1007 of this issue).

The Air Almanac

THE British "Air Almanac" and the "American Air Almanac" have now become a single publication under the title "The Air Almanac", which will be published three times yearly, each issue containing the requisite data for four months. The first issue of this joint enterprise is for January–April 1953 (Air Publication 1602; pp. 242+56. London: H.M.S.O.; Washington, D.C.: U.S. Naval Observatory. 1952; 10*s*.). It is produced jointly by H.M. Nautical Almanac Office, the Royal Greenwich Observatory, and the Nautical Almanac Office, United States Naval Observatory, but it is printed separately in England and in the United States. Although the unification of the two former publications has necessitated a number of minor changes in both, these will be obvious to those who use "The Air Almanac", and navigators who have been familiar with either almanac will find no difficulty in using the new production. Very full explanations are given, and in order to make the almanac more satisfactory for international use a list defining the symbols and abbreviations that are used is given in English, French and Spanish. The International Civil Aviation Organization accepted the new publication as the basis of an international air almanac, and it seems probable that it will be reproduced, with language changes, in France. It is hoped that it will eventually become international.

Preservation of a Saxon Wooden Bucket

IN the October issue of the *Museums Journal*, Dr. A. A. Moss, of the Research Laboratory of the British Museum, relates with illustrative photographs the remarkable achievement of the preservation of a Saxon bronze-bound wooden bucket with an iron handle. The bucket, when found in Wiltshire, consisted of water-logged staves of yew maintained in position by wet chalk. The four bronze bands were broken. The bucket was immersed in water to prevent shrinking and the chalk removed. The wooden staves were found to be very fragile and the bronze bands corroded. It was deemed necessary to take the bucket to pieces and treat the wood and bronze separately. The corrosion products were removed from the bronze bands and from the supporting strips by electrolytic reduction in a 5 per cent solution of sodium hydroxide. This loosened the rivets, which could then be easily removed. After soaking in water to free from chloride, the fractured edges were joined with soft solder. To preserve the shape of the wood it was decided to replace the water in the cells by alum. Eventually, after drying, the surface of the wood was painted with a dilute solution of cellulose nitrate. In re-assembling the wood and the bronze, a circular bottom for the bucket was made out of 'Perspex'; this fitted into the grooves in the staves. 'Durofix' was used for re-assembling the wooden portions.

The Post-fledging Dispersal of Juvenile Titmice

THE post-fledging dispersal of juvenile titmice was studied by Ivan M. Goodbody in the summer of 1950 in a piece of mixed deciduous woodland near Oxford (*British Birds*, 45, No. 8; August 1952). 248 young bluetits and 191 young great tits were marked with a colour ring on each leg, so that all the birds hatched in the study area could be identified as such, wherever seen. Regular counts of the number of ringed and unringed tits were made in the study area and in a strip of woodland outside it, and showed that an explosive dispersal of young birds takes place within a week or two of leaving the nest; thereafter birds continue to move outwards from their birthplaces. A marked rise in the percentage of unringed juveniles both in the study area and in the outside area in mid-August indicates the possibility that there may be a passage of juveniles at about this time. While no ringed birds were found in a large woodland area one mile away, several were located in low-lying water meadows half a mile away.

Solanaceous Alkaloids in Normal and Grafted Plants

IN normal plants of *Atropa belladonna* the ratio of hyoscine to hyoscyamine is approximately constant at a value of 0·12, irrespective of the total alkaloid present in the plant, the part of the plant analysed, or whether the plant is aged or starved. By contrast, in the normal plants of *Datura innoxia* this ratio is high (average 9·71; tap roots 13·81–17·36; other parts 4·6–9·8). In grafted plants the scion always contains the alkaloids in the proportions characteristic of the plant used as stock, not in those of the scion species. It thus appears that the alkaloids are synthesized in the roots, particularly in the young growing tips, and that they are transported unchanged, probably in the transpiration stream, into the shoot. These results have been obtained using partition chromatography, the extracts tested being of plants into which no foreign alkaloids had been introduced (see G. M. James and B. H. Thewlis. *New Phyt.*, 51, 2, 250; 1952).

A Lower Devonian Charophyte

A NEW species of *Trochiliscus* (Charophyta) from the Downtonian (Lower Devonian) of eastern Europe, described and illustrated by some good photographs by W. N. Croft (*Bull. Brit. Mus. Nat. Hist.* (Geology), 1, No. 7, 1952), probably affords the earliest reliable record of an undoubted Charophyte. It is considered that this species was probably a land plant, growing like the recent and contemporary *Charas* in fresh and brackish water.

Central American Flora

THE very rich floristic region of Central America has long attracted taxonomic botanists. In a recent work ("Flora of Guatemala", by P. C. Standley and J. A. Steyermark. ***Fieldiana:*** Botany, 24, Pt. III. published by Chicago Natural History Museum, April 1952), the authors have dealt with the major monocotyledonous families from Commelinaceæ and Pontederiaceæ to Cannaceæ and Burmanniaceæ, and with dicotyledonous families including Casuarinaceæ and Piperaceæ to Fagaceæ and Urticaceæ. Some excellent line-illustrations accompany the text.

Sunspots during January–April 1952

AN account by Lucy T. Day of the positions, areas and counts of sunspots during the period January–April 1952 is given in United States Naval Observatory Circular No. 36 (June 18, 1952). The results, tabulated in seven pages of the Circular, are based upon measurements made at the Naval Observatory on plates secured there or at the Mt. Wilson Observatory, and are a continuation of those published in the *Monthly Weather Review* from February 1, 1927, to December 31, 1947. An explanation is given of the meaning of the various symbols used in the seven columns, and at the end of each month the mean daily area and the mean relative sunspot number are given.

Colonial Service: Recent Appointments

THE following appointments in the Colonial Service have recently been announced: W. E. M. Logan (assistant conservator of forests, Kenya), regional assistant conservator of forests, Tanganyika; P. S. Hammond (agricultural officer, Gold Coast), assistant director of agriculture (cocoa industry), Gold Coast; J. B. D. Robinson (chemist, Department of Science and Agriculture, Barbados), scientific officer, agricultural chemist, Kenya; J. M. Waterston (senior botanist, Nigeria), principal research officer, Agriculture Department, Nigeria; G. C. Witt (soil survey officer, Trinidad), soil chemist, Trinidad; Dr. S. E. Piercy (senior veterinary research officer, Kenya), chief veterinary research officer, Kenya; J. F. C. Swan (senior veterinary officer, Northern Rhodesia), chief animal husbandry officer, Northern Rhodesia; S. B. Chambers (statistician, Nigeria), government statistician, Nigeria; H. A. Darby, R. E. Osborne and I. H. Tomlinson (agricultural officers, Jamaica), senior agricultural officers, Jamaica; H. C. Poisley (assistant government pharmacist, Fiji), government pharmacist and medical storekeeper, Fiji; G. E. Redshaw (agricultural assistant, Jamaica), agricultural officer, Jamaica; R. O. Williams (agricultural officer, Kenya), chief research officer, Agricultural Department, British Guiana; W. H. Andrews and D. A. L. Brown, agricultural officers, Tanganyika; R. E. H. Atkinson, agricultural officer, Uganda; A. M. Cockburn, agricultural officer, Nigeria; J. R. Dunsmore and M. J. Smith, agricultural officers, Federation of Malaya; J. R. Peberdy, agricultural officer, Kenya; J. W. Reed, agricultural officer, Nyasaland; E. A. Riley, plant pathologist, Northern Rhodesia; G. Fry and J. S. Spears, assistant conservators of forests, Kenya; E. Williams, geologist, Uganda; Miss H. G. T. Maycock, pathologist, Federation of Malaya; J. Riley, scientific officer (entomologist, W.A.P.I.R.U.), Nigeria; J. Smartt, plant breeder/scientific officer, Northern Rhodesia; M. C. Butler, veterinary officer, Kenya; R. H. Johnson, veterinary education officer, Nigeria; A. Beaton, assistant conservator of forests, Uganda; M. J. Berry, assistant conservator of forests, Federation of Malaya; B. M. Brown, meteorologist, West African Meteorological Service, Nigeria; J. A. Channon, meteorologist, East Africa High Commission; P. B. Cornwall, entomologist, West African Cocoa Research Institute, Gold Coast; H. F. Lamprey, biologist, Game Department, Tanganyika; W. McC. Lyall, field geologist, Kenya; P. F. Neal, field officer, Geological Survey Department, Uganda; C. J. Swanson, meteorologist, East Africa Meteorological Department, East Africa High Commission; D. C. Upton, statistician, East Africa High Commission; J. A. Willby, livestock officer, Tanganyika; A. C. Williamson, assistant conservator of forests, British Honduras.

Announcements

PROF. P. M. S. BLACKETT, Langworthy professor of physics in the University of Manchester, has been appointed to the University chair of physics tenable at the Imperial College of Science and Technology, London. The title of reader in organic chemistry in the University has been conferred on Dr. L. N. Owen in respect of the post held by him in the Imperial College.

PROF. JAMES CHESTER BRADLEY, professor emeritus of entomology, Cornell University, one of the United States representatives on the International Commission on Zoological Nomenclature since 1914, has been elected president of the Commission, in succession to the late Dr. James Lee Peters, Museum of Comparative Zoology at Harvard College, Cambridge, Mass.

SIR CHARLES DARWIN has been appointed chairman of the Radioactive Substances Advisory Committee in succession to Sir Henry Dale, who has resigned. Prof. G. R. Cameron (University College Hospital Medical School) and Prof. K. G. Emeléus (Queen's University, Belfast) have been appointed to the Committee.

THE fourth annual conference of the Society for the Study of Fertility will be held in the University of Liverpool during July 7–8, 1953. Further particulars can be obtained from the honorary secretary, Dr. G. I. M. Swyer, at University College Obstetric Hospital, Huntley Street, London, W.C.1.

AT a meeting of former members of the late Scottish Seaweed Research Association, those present determined to form a Society to be known as the Seaweed Utilization Society, to serve as a two-way channel of information and opinion with the Institute of Seaweed Research. The secretary of the Society is Miss M. D. Walker, 49 Rodney Street, Liverpool 1.

THE Oil and Colour Chemists' Association will hold its 1953 conference at Eastbourne during June 2–6. The general theme will be "The Optical Properties of Films of Surface Coating Materials", and there will be three technical sessions, each of three papers, on the mornings of June 3–5. Hotel reservations must be completed before January 1 on the appropriate form, obtainable from the general secretary of the Association at Memorial Hall, Farringdon Street, London, E.C.4.

APPLICATION OF RADAR TO METEOROLOGY

CONFERENCE IN MONTREAL

THE third Radar Weather Conference was held in the Macdonald Physics Laboratory of McGill University, Montreal, during September 15–17. About eighty people actively engaged in research into the application of radar to meteorological problems attended, and some forty papers were read and discussed in seven sessions. A very useful feature of the Conference, which contributed greatly to the value of the discussions that followed each paper, was the provision, before the beginning of the first session, of copies of all the papers scheduled to be read. When it is noted that the time-limit for receipt of authors' manuscripts was only three weeks in advance of the meeting, it is clear that Drs. Marshall, Gunn and Hitschfeld, of the Stormy Weather Research Group, McGill University, who formed the conference committee, accomplished a notable feat of organization.

The subject of Session *A*, under the chairmanship of Mrs. P. M. Austin (Massachusetts Institute of Technology), was "Precipitation Mechanisms". It is now more generally recognized that the Bergeron–Findeisen theory of rain formation—the rapid growth of ice crystals in an atmosphere saturated with respect to water, followed by growth by collision with cloud particles—is not adequate to explain all cases of rain formation, and that growth to raindrop size, without the aid of an ice crystal, by coalescence in the liquid state must also occur. The relative importance of each mechanism in a particular weather situation is, however, still a matter of speculation. That radar may be of great assistance in resolving this problem was shown in papers by Wexler (Massachusetts Institute of Technology), Battan (University of Chicago) and Cunningham (Massachusetts Institute of Technology). From data on the level at which radar echoes from thunderstorms first appear and their subsequent rate of growth, Battan concludes that rain formation in convective clouds, even those extending above the freezing level, may often occur through a process involving only the liquid phase. On the mechanism of this process, East (McGill) suggested that, if by some method—for example, turbulence or steady acceleration of the air—the gravitational field around a cloud droplet is increased, then the rate of growth of that droplet by collision with smaller droplets will also increase. Hence turbulence may play an important part in the generation of rain in cumulus clouds.

Turbulence as it affects aircraft rather than cloud droplets was the subject of a paper by R. F. Jones (Meteorological Office, East Hill). It was shown that the structure of the echo from a cumulus or cumulo-nimbus cloud, as seen on the radar display tubes, particularly in the vertical cross-section, is a useful guide to the severity of the turbulence likely to be encountered by an aircraft traversing the cloud and also indicates the places in the cloud where the turbulence is likely to be the most severe.

Marshall, Langleben and Rigby (McGill), from an examination of the characteristic 'mare's tail' radar echo-pattern (seen in the vertical cross-section) associated with falling snow, suggested that snow is generated continuously in compact generating elements rather than uniformly over a wide area.

Session *B*, under the chairmanship of Prof. H. Byers (University of Chicago), was devoted to "Cloud Observations and Cloud Radar Problems". Whereas radars operating on wave-lengths of 10 cm. and 3 cm.—the only wave-lengths commonly used for weather purposes up to this time—detect only those parts of clouds containing rain or drizzle drops or snowflakes and not the whole clouds, Plank, Atlas and Paulsen (U.S. Air Force Cambridge Research Centre), using a vertically-looking radar of wave-length 1·25 cm., reported that about 47 per cent of all clouds can be detected. Swingle (Signal Corps Engineering Laboratories), with a vertically-looking 0·86-cm. radar, has obtained better results than on 1·25-cm. wave-length on cumulus, cirro-stratus and cirrus clouds, and about the same results on other clouds. The results obtained are in accordance with the Rayleigh scattering theory, so that even these radars of shorter wave-lengths see only the parts of clouds containing the larger elements. Nevertheless, the ability to detect smaller droplets or ice crystals than with wave-lengths of 10 and 3 cm. will add further to the knowledge already gained of precipitation processes.

Session *C* was held in the Council Chamber of the International Aviation Building, with Mr. A. C. Bemis (Massachusetts Institute of Technology) as chairman. The purpose of this session was to bring together the radar meteorologists and those interested in the possibilities of using airborne radar to increase passenger safety and comfort. Carnes (Aeronautical Radio, Inc.) put the airline point of view, and pointed out that economical operation demands that the size and weight of electronic equipment carried must be kept small. He said that 3-cm. airborne radar suffers too much from attenuation in heavy rain, and a wave-length of 6 cm. is being recommended. Tolefson (National Advisory Committee for Aeronautics) showed that the use of radar will enable the pilot of an aircraft significantly to reduce the number of large gusts it encounters with increased passenger comfort, a finding which is supported by the work done in Britain. It is unlikely, however, that radar could assist in reducing the number of small gusts encountered, a factor of importance to structure fatigue.

"Rain Measurements" was the subject of Session *D*, over which Mr. D. Atlas (U.S. Air Force Cambridge Research Centre) presided. 10-cm. or 3-cm. radar has the useful property of indicating over a surrounding area almost instantaneously—in the time taken to sweep the radar beam over the area—the places where precipitation is occurring, and, from the intensity of the received radar signal, an indication of the rainfall intensity can be obtained. In areas where very heavy rainfall over the catchment area of a river leads to dangerous flooding farther down, the warning which radar can give may be of great value in saving lives and property. Research along these lines was reported by Stout and Neill (Illinois State Water Survey), who claimed that rainfall-rates computed from the received signal intensities of a 3-cm. radar were as accurate as those obtained from a rain-gauge network of 1 gauge per 200 square miles.

Similar results using 10-cm. radar, with a pulse integrator device which gives automatically the average signal intensity over an area, were reported by Austin and Richardson (Massachusetts Institute of Technology).

Mr. G. E. Stout (Illinois State Water Survey) presided over Session *E*, which was devoted to "Instruments". As well as the radars of short wave-length already referred to, which it is hoped to use as indicators of cloud base and top, instruments were described which are designed to measure rain-drop sizes and distributions from aircraft and on the ground. A knowledge of liquid water content and drop-size distribution is of importance in assessing quantitatively the radar signal received from a volume of cloud.

Dr. R. A. Smith (Telecommunications Research Establishment, Malvern) was chairman of Session *F*, when "Scattering in the Atmosphere" was discussed. Gunn and East (McGill) and Labrum (Radiophysics Laboratory, Sydney), working independently, have put on a firm quantitative basis the theory of back-scattering of radio energy from ice spheres coated thinly with water and from water spheroids. They have proved (what up to now has been assumed) that a small ice sphere with a thin water coating, as, for example, in the first stage of melting, will scatter nearly as well as a water sphere of the same volume and may absorb better. A water-coated ice spheroid may scatter and absorb very much more strongly than the spherical water drop into which it melts, giving an explanation of the well-known 'bright band' effect of enhanced echo at the freezing-level in conditions of continuous rain.

Gerhardt (University of Texas) said that his refractometer measurements indicated that in subsidence and frontal inversions the refractive index gradient over short distances may be several orders of magnitude greater than the normal, and that isolated patches exist with variations of refractive index adequate to explain 'angel' echoes (radar echoes received from a clear sky). Gordon (Cornell University) explained how scattering from turbulent patches in the atmosphere may increase the field strength beyond the horizon above the theoretical value at frequencies greater than 30 Mc./s., as has often been observed. There was some discussion on 'angel' echoes, which were reported by W. B. Gould (Signal Corps Engineering Laboratory) to have been observed in great numbers using a vertically-looking radar of wave-length 1·25 cm. These echoes are also observed in Britain using wave-lengths of 3 cm. and 10 cm. and are almost certainly associated with inhomogeneities in the atmosphere of the kind described by Gerhardt.

The final session, under the chairmanship of Dr. Gould, discussed "Fluctuating Signals", the object of this topic being to deduce some of the properties of the scattering particles by measurement of the fluctuations from pulse to pulse of a radar signal. In particular, it is hoped that the measurements may yield information on the turbulence within a cloud—for example, the size and duration of turbulent eddies. The subject is clearly complicated by the large distribution of drop sizes within a precipitating cloud and also by the inherent variabilities in the performance of radar sets.

Before finally dispersing, the Conference decided to accept an invitation to hold its fourth meeting during November 1953 in the University of Texas.

R. F. JONES

INTERNATIONAL SCIENTIFIC FILM ASSOCIATION

SIXTH ANNUAL CONGRESS

THE growing strength of the international scientific film movement was well in evidence at the annual congress of the International Scientific Film Association, held in the Maison de la Chimie, Paris, during September 23–October 1. During the congress, the acceptance of three countries as new members was announced—Cuba, East Germany and West Germany—and the reports from all countries showed steady progress and development in the use of the film for scientific education, for research and for popularizing science.

Seventy-two delegates and observers, representing twenty-one countries, the United Nations Educational, Scientific and Cultural Organization, the Fédération Internationale des Archives du Film and the Fédération Internationale des Ciné-Clubs, attended the congress. During the meeting, a hundred and seventeen films were shown to public and specialized audiences and, of these, the largest number from any one country was from Great Britain, no fewer than twenty-seven British films being shown; among them may be particularly mentioned "Atoms at Work", the Crown Film Unit's ten-minute documentary on Harwell, which attracted wide interest and resulted in a unanimous resolution by the congress urging other countries to give it the widest showing and to make similar films depicting their own development of atomic energy for peaceful ends.

Other films shown included a West German film illustrating, by means of infra-red photography, the remarkable fact that mice will fight savagely in the dark but never in the light; a French film showing the film work by the late Bernard Lyot on astronomy; a quite outstandingly beautiful Hungarian colour film of bird and insect life on the great lakes; an Icelandic film made by Mr. Tutte Lemco on the eruption of Mount Hecla, the dramatic shots of which provoked several bursts of spontaneous applause; and an equally striking Italian colour film of the courtship of the praying mantis.

The Research Section of the Association held several sessions, at one of which there was a demonstration of magnetic strip recording by M. André Didier, which was of particular interest to the British members present in view of its introduction at the present time into Britain. There were also two demonstrations of stereoscopic techniques. The first, by Dr. François Savoye (Paris), dispenses with 'Polaroid' glasses and relies on a synchronized rotating 'grill' in front of the screen to alternate the right- and left-eye images. It was effective, but suffered from the fact that the viewer's head has to be held very still in order to avoid a shifting of the images—a drawback that may possibly be due to the fact that both screen and grill were rather small. The other stereoscopic system was demonstrated by H. Dewhurst, of the Telecommunications Research Establishment, Malvern, using 'Polaroid' glasses and a beam-splitting equipment which is within the scope even of the amateur film-maker. The demonstration was mainly with an amateur colour film, and the results were excellent, although again handicapped perhaps by a small screen.

Among matters discussed by the general assembly of the congress was a proposal to establish a Section of the Association to deal with veterinary science, a suggestion which was made by the Netherlands delegation and accepted by the assembly. It was also decided to consider the possibility of holding at the 1953 congress a special session on high-speed cinematography.

The officers of the Association elected unanimously for 1952–53 were as follows: *President*, John Maddison (Great Britain); *Vice-Presidents*, Jan Korngold (Poland) and Prof. Mario Ponzo (Italy); *Honorary Treasurer*, J. W. Varossieau (Holland); and *Honorary Secretary*, Jean Painlevé (France). In addition, Luc Haesaerts (Belgium) was re-elected as curator of the International Film Reference Library and Prof. R. V. Talice (Uruguay) was appointed as delegate for Latin America; Dr. G. Wolf (West Germany) was elected chairman of the Research Section, and Prof. Dekking (Holland) chairman of the Medical Section.

Great Britain was represented at the congress by a strong delegation led by Dr. Malcolm Donaldson, which also included Prof. H. Dryerre, representing the Scottish Scientific Film Association. At the end of the final session of the Assembly, it was unanimously agreed to accept the invitation of the British delegation to hold the seventh congress in London during September 1953. J. STEWART COOK

INSULATION OF ELECTRICAL EQUIPMENT

A VACATION 'school' on the insulation of electrical equipment was held in the Electrical Engineering Department of the Imperial College of Science and Technology, London, during September 15–19. It was attended by some eighty engineers drawn from industry, the British Electricity Authority, research associations, technical colleges and the universities. The purpose of the course was to consider the factors which are limiting insulation design in the main classes of electrical equipment, and the general principles which should govern the approach to the solution of outstanding problems in this field.

An opening address was given by Dr. P. Dunsheath, chairman of convocation of the University of London, in which he commented on the value of postgraduate schools in facilitating and extending the interchange of knowledge and ideas between specialists of long experience and the more junior members of industry and in reducing the time-lag in the use of new information. He then drew on his long experience of cable manufacture in an interesting historical review of early developments in insulating materials and of the difficulties which were encountered and overcome when little was known of the principles underlying their behaviour.

In the first lecture Prof. Willis Jackson, of the Imperial College of Science and Technology, London, discussed the problems facing the insulation engineer, surveyed the historical development of the widely used materials based on natural products and of the more recent synthetic materials, and outlined the progress which has been made towards explaining the electrical, physical and mechanical properties of these materials in terms of their chemical composition and physical structure. He was followed by Dr. L. Hartshorn, of the Electricity Division, National Physical Laboratory, Teddington, who spoke on the phenomena of permittivity and dielectric loss, with particular reference to the effects on them of temperature, humidity and oxidation.

The third lecture, by Dr. S. Whitehead, director of the Electrical Research Association, dealt in a comprehensive manner with existing knowledge of the mechanisms of intrinsic and thermal dielectric breakdown, and of breakdown due to external or internal discharges. Dr. Whitehead also discussed the effect on the electric strength of electrochemical deterioration in service, and the scope for improvement in materials, design and testing. Another member of the Electrical Research Association, Mr. C. G. Garton, then spoke on the structural basis of electrical and mechanical properties, and gave a very illuminating treatment of rate processes in relation to the dependence of these properties on temperature and frequency.

In the fifth lecture Mr. R. Snadow, of the British Thomson-Houston Co., Ltd., reviewed the available insulating materials in terms of the present thermal classification. He emphasized the inadequacy of this classification for some of the new synthetics, and that their application is being retarded by too limited knowledge of their thermal endurance.

The next five lectures were concerned with the applications of insulation in different classes of electrical equipment, and with the design problems involved. In discussing communication components, Mr. I. M. Ross, of the Ministry of Supply, referred to the extremely wide frequency-range with which the communication engineer has to deal, and the severe thermal and mechanical conditions to which military communication equipment, in particular, is subjected. After reviewing the changes in design which the use of new synthetic materials has made possible during recent years, he outlined the directions in which further improvement is required. Dr. L. G. Brazier, of British Insulated Callender's Cables, Ltd., dealt with the development of high-voltage cables and remarked that, in consequence of improvements which have occurred in the qualities of paper and oil and in the methods of cable fabrication, the oil-paper dielectric introduced by Ferranti some fifty years ago remains the only form of dielectric suitable for use at the highest operating voltages. He outlined the outstanding problems and the methods being adopted to resolve them. The design of power capacitors, and the manner in which this might be affected in the near future by the use of the new ceramics based on barium titanate, was then discussed by Dr. R. S. Vincent, of British Dielectrics Research, Ltd.

Mr. E. Jones, of the English Electric Co., Ltd., made a comprehensive review of the insulation problems involved in the design of electrical machines and indicated possible lines of approach to a more efficient use of insulation, and the reasons why, except to meet special requirements, there is no great need for, nor likelihood of, a marked increase in operating temperatures. The subject of transformers was dealt with by Mr. D. McDonald, of the British Thomson-Houston Co., Ltd. After discussing the electrical, mechanical and thermal requirements of transformer insulation design and the problems involved in satisfying them, he illustrated the trends of high-voltage transformer design by consideration of the shielded cylindrical layer-type winding. He brought out the increasing similarities with cable construction and the movement towards the exclusive use at the highest voltages of the oil – paper dielectric. Mr. P. G. Ashley, of the Metropolitan-

Vickers Electrical Co., Ltd., then discussed the insulation of switchgear. He surveyed the main uses of insulation, for supports, fillers and coverings, and the suitability of available materials for these purposes and, after emphasizing the need for fuller information concerning the long-term stability of materials and the difficulties of obtaining it, concluded by remarking that technically, if not economically, 500-kV. switchgear is a feasible proposition.

The final lecture, by Dr. J. S. Forrest, of the Research Laboratories of the British Electricity Authority, was concerned with the testing of insulation in the laboratory, factory and field. He classified the tests in use according to their function and advised on the interpretation of test results; he emphasized the need for constant review of the methods of test directed towards the formulation of a scheme of testing which would reflect the service conditions to be met as faithfully as possible He remarked that such an approach would assist in improving the present inadequate correlation between laboratory, factory and field tests.

The specialized discussions which followed the individual lectures were supplemented by a general discussion during the final session, when attention was devoted to questions such as the availability of new materials; the inadequacies of the present classification; the much more satisfactory understanding of the electrical mechanisms of dielectric behaviour compared with those governing the physical and mechanical properties, and finally, the desirability of increased and more fundamental attention to materials in courses leading to degrees and national certificates in electrical engineering. Visits were made during the course to the laboratories of the Electrical Research Association and the British Insulated Callender's Cables, Ltd.

BRITISH SCIENTIFIC INSTRUMENT RESEARCH ASSOCIATION

OPEN DAYS

WITH whatever feelings one regards the advancing front of science, it is obvious that the operation of new processes and new techniques, which give force to ideas and actions based on them, is maintained and nourished by the development of scientific instruments. These are tools of industry as well as of research. Thus the practice of the art and craft of instrument-making is a key industry, and it is significant that the British Scientific Instrument Research Association was the first of the industrial research associations, being founded in 1918. The laboratories of the Association are situated near Chislehurst in park-like surroundings, and when members and friends were entertained there on the recent open days (November 5 and 6) the weather was mild and clement enough to reinforce the pleasure of the occasion.

For thirty years the work of the Association was carried on in a house in Russell Square, London, and was mainly concerned with the manufacturers of optical instruments. This is not the place to report on the vicissitudes and difficulties of the early years, but in the outcome there has been very considerable development. During and since the Second World War the membership has greatly expanded, as has the scope of the experimental work undertaken, and the facilities provided at Chislehurst are comprehensive and impressive. No great powers of observation are required by the visitor to confirm that the Association is an integral part of the scientific instrument-making industry.

Research associations, though having essential similarities, differ markedly from one another in a variety of ways which reflect the character, scope and state of scientific development of the industries which they serve. Some of them are able to concentrate on the behaviour and manipulation of narrow groups of raw materials or types of processes on which their industries depend. In this sense the field may be relatively narrow, or at least the boundaries may be reasonably well defined. The British Scientific Instrument Research Association must have a broader outlook, for it serves an industry which itself serves a great variety of other industries, and to these must be added the Armed Services, universities and scientific establishments of all kinds. In general, of course, testing and instrumentation are subjects on which a considerable contribution is made to individual industries by their respective research organizations, but there remains an extensive region for activity by the Association.

The original and continuing emphasis on optical work was illustrated during the open days by demonstrations of lens grinding and, judging from the interest displayed by visitors, many people were impressed by the speed and accuracy with which this can be accomplished to precise specifications by precision engineering set-ups. The Association has a small glass-making shop (a palette of colour glasses for artificial eye-making was displayed) and has made considerable contributions to the techniques of chemical analysis of optical glasses, as well as to the examination of such glasses by interferometry, polarimetry and microscopy, including the effects of ageing and attack by humid atmospheres, etc.

The utilization of modern synthetic resins in optical cements has evidently been developed with much satisfaction, and there were striking demonstrations of the preparation of polarizing films from suitable synthetics by molecular orientation, and of metallic mirrors, anti-reflexion films, interference filters for visible light, heat filters, etc., dependent on high-vacuum evaporation techniques.

The development of infra-red transparent materials has made a striking advance through the utilization of the fact (known for some time) that mixed crystals of thallium bromide and iodide are transparent to radiations in the region 0·5–40 μ. The process was demonstrated of growing single crystals in vertical cylindrical crucibles by a progressive freezing of the melt from bottom to top. The material, known as *KRS*-5, can be ground and polished and is chemically stable.

Graticule production may be described as one of the Association's 'specialities'. The methods adopted are mainly photographic in character and were well illustrated, together with the preparation of resolution test-slides for projection lenses.

Relatively recently, with the increasing use of electronic devices, the Association has built up a department well equipped to deal with a variety of electrical problems, exemplified by work on thermionic valves and valve amplifiers, electrometer valves, resistors of low temperature coefficient, magnetic amplifiers, the effects of dust on electrical contacts, etc. By contrast with the apparent complexities of electronic work, there was also displayed in another room the success so far achieved in attempting to answer the simply stated question: How can one ensure free movement of mercury drops in sealed glass tubes such as are used in rocker contacts on electrical relays, etc., so as to avoid faulty make-and-break?

Studies on the gas permeability of thermocouple sheaths, performance specifications for electric ovens, fluid flow of liquids and gases, and the use of pneumatic (air-jet) gauges for observations on the curvature and thickness of lenses, provided further evidence of the wide scope of the Association's activities.

There were many indications of the flexibility of the broad divisional organization of the laboratories, supported by excellent drawing-office and workshop facilities. One learned that all divisions contribute to the information and liaison services, partly by providing background for the Information Department in dealing with technical inquiries, and partly by visits to member firms to study works procedures, to discuss immediate practical problems, and to seek advice about investigations being carried out by the Association. It is noteworthy that heads of divisions and senior staff generally are expected to spend some 20 per cent of their time in such visiting.

It would seem that those member firms which enter into active membership of the British Scientific Instrument Research Association in all its aspects may benefit exceedingly.

ALLEGHENY OBSERVATORY, UNIVERSITY OF PITTSBURG

A SHORT account of the origin and development of the Allegheny Observatory of the University of Pittsburg (pp. 12; from the University) has been compiled by Theodora M. Lauterbach, which makes very interesting reading. The appearance of Donati's Comet in 1859 aroused a new interest in astronomy, and a group of Pittsburg business men soon organized the 'Allegheny Telescope Association' and made plans for the purchase of a large telescope. This 13-in. refractor was made by Fitz, of New York, and was installed in the new building complete with dome, on a hill in the old city of Allegheny which later became part of Pittsburg. In 1867 the Association presented the telescope and building to the Western University of Pennsylvania—now the University of Pittsburg—and in the same year Samuel Pierpont Langley went to Pittsburg as professor of astronomy and director of Allegheny Observatory. Under him, and through financial assistance from William Thaw, a Pittsburg industrial leader, the equipment in the Observatory was greatly improved.

John A. Brashear, a former mill-worker, who had shown a wonderful aptitude for making lenses, and who was encouraged in this work by Langley, played a prominent part in the development of the Observatory. When James E. Keeler, who succeeded Langley in 1891, resigned in 1898 to take up the directorship of Lick Observatory, Brashear became temporary acting director until the following year, when F. L. O. Wadsworth took charge. During the latter's period as director, most of his time was devoted to supervising the construction of the buildings and instruments for the new Observatory, and with Brashear's assistance their efforts were rewarded by the laying of the foundation stone in October 1900. In 1912 the new Allegheny Observatory was dedicated and presented to the University of Pittsburg, and Dr. Frank Schlesinger was appointed director.

The account describes the excellent work of Schlesinger and the succeeding directors—Curtis, Jordan and others—and, as the author says at the end of this interesting brochure, "The Observatory's location serves well for uninterrupted research, and it is through research that Allegheny Observatory has helped to make the University of Pittsburg known throughout the world". The publication contains thirteen photographs of directors, instruments, and portions of the Observatory buildings.

NUFFIELD FOUNDATION

ANNUAL REPORT

THE seventh report of the Nuffield Foundation covers the year ending March 31, 1952*, and is the third in the current period of the present programme, during which allocations totalling £620,311 have been made for fundamental research in the United Kingdom; of this, £189,261 is for biological and £189,950 for sociological studies, and £110,000 is reserved for research overseas in the Commonwealth, of which £40,190 has been allocated in Australia, £12,712 in New Zealand and £18,500 in South Africa. The cost of existing schemes to the end of the quinquennium is estimated at the £498,892 already set aside, while £112,921 has been devoted during the current quinquennium to the continuance and extension of projects in medicine, science and the care of old people begun in the first programme. From the Oliver Bird Fund, £114,000 has been used or reserved for research in rheumatism.

By thus reserving in advance from current income £1,504,849 of £1,596,042 allocated in grants for the quinquennium, the Foundation seeks to assure itself of future freedom in the event of any fluctuations either in income or objectives and opportunities. For the advancement of research in the United Kingdom the Foundation has been concerned chiefly to stimulate studies in biology and sociology and, outside these two fields, any other research of real importance or promise which lacks the funds required for its full development. For financing projects of this latter type, the Foundation has set aside a sum which is termed the 'free fund', the use of which is essentially unplanned, and from this fund grants totalling £241,000 have been allocated during the past year. The greater part of this is to meet the Foundation's commitment to share with the Department of Scientific and Industrial Research the cost of the steerable radio telescope at the Jodrell Bank Experimental Station of the University of Manchester. This grant will avert the postponement of the project because sufficient public funds could not be made available. Grants from the same fund have been made to the University of Cambridge towards the cost of sinking and lining a borehole at or near the geophysical laboratories for experiments and measurements deep into the earth's crust, and towards the construction, during the next five years, of a new and improved high-speed electronic calculating machine. A three-year grant has also been made to Prof. J. Rotblat, of the Physics Department, St. Bartholomew's Hospital Medical College, to enable him to retain two technicians specially trained in the photographic emulsion technique he uses in his study of nuclear energy states, and a grant of £14,000 has been made to the Royal Anthropological Institute for the establishment for five years of the Nuffield blood-group research and reference centre, which came into operation on January 1, 1952.

---

* Nuffield Foundation. Report for the Year ending 31 March 1952. Pp. 162. (London: Nuffield Foundation, 1952.)

Grants totalling £95,492 promised during the year for biological studies include those to the University of Cambridge for theoretical investigations at the Chemical Laboratory on molecular structure with the view of their application to biological problems and the study of animal behaviour, particularly studies of imprinting, habituation, insight and homing orientation at the Madingley ornithological field station; to the University of Leeds for studies on the molecular structure of collagen and infra-red techniques in the Department of Biomolecular Structure; and to the Lister Institute of Preventive Medicine to enable investigations on the isolation and characterization of antigens to be resumed and for the continuance of the work on co-enzyme A and related substances. Grants have been made to the University of London to increase the biological balance of the team working in the Wheatstone Physical Laboratory at King's College, under Prof. J. T. Randall, on the structure and function of nucleic acids in cells and the structure and fibrogenesis of the collagen of connective tissues; for the work on the embryonic brain at the Department of Anatomy and Embryology, at University College; and for the work on proliferation and morphology in the adult in the same Department, in association with the Department of Physiology; while grants have also been made to the Department of Clinical Pathology of University College Hospital Medical School for work on the red cells of human blood and to the Department of Morbid Anatomy for work on the responses to injury, and subsequent repair and regeneration, in liver and other tissues; the Obstetric Unit of the same School has received a grant for assisting the application of the sensitive electronic recording apparatus required for the further development of the work on the normal pattern of uterine contractions in child-birth and the effects of drugs on the contractions.

A grant of up to £4,000 has been made to the University of Manchester to enable Dr. H. C. B. Slack to investigate the metabolism of the extracellular substances of the body at the Rheumatism Research Centre. The University of Oxford has accepted grants for the continuance of work at the Physical Chemistry Laboratory on the mechanism by which resistance to various drugs and antibodies of a bacterial population is increased; for a graduate assistant to Dr. W. Holmes, of the Department of Zoology and Comparative Anatomy, to extend, along histological, histochemical and biochemical lines, his work on the adrenal cortex in lungfish; and for building up in the same Department a research unit in animal behaviour. A grant has also been made to enable the Strangeways Research Laboratory, Cambridge, to provide a worker trained in tissue culture and histology to collaborate with the Sir William Dunn Department of Biochemistry, University of Cambridge, in work on the effect of insulin and other hormones on the rudimentary long bones and animal tissues grown in tissue-culture.

The Foundation's grants for sociological studies are aimed primarily at aiding non-economic subjects, but two recent grants have been made for applied economic research: one of £6,500 to the Department of Applied Economics, University of Cambridge, is to collect and construct the social accounts of Cambridgeshire; the other, of £11,500, is to the Institute of Statistics, University of Oxford, for a national sample-survey of personal savings, to be carried out in two succeeding years. Both these projects have strong social implications and will make use of sample-interview techniques, thus contributing to the further development of this essential tool of social research. Grants totalling £3,200 have been made to the Department of Social Anthropology, University of Edinburgh, to finance work under Dr. Kenneth Little on the organization of Colonial students in London, their educational activities, etc., the social organization of coloured people in Manchester, and, in West Africa, on the complex social and economic factors which give rise to emigration and direct it to Britain. A grant has been made of £3,500 for the creation, for five years, of a research fellowship at Bedford College, University of London, to be held by Mrs. Barbara Wootton to review the whole field of social research. A grant of £4,000 has gone to the Department of Town Planning, University College, London, for a two-year study of the contribution of the social sciences to the principles and techniques of town and country planning and a survey of the processes of planning.

From the Oliver Bird Fund a further grant of £4,000 will enable the team under Prof. M. Stacey, in the Department of Chemistry, University of Birmingham, to continue for two or three years its studies of the organic chemical structure and enzymatic behaviour of the tissue components and joint fluids. The grant of £1,100 for the examination of the steroids of ox-bile, the original source of cortisone, under Prof. F. S. Spring at the School of Chemistry, Royal Technical College, Glasgow, has been renewed for a further two years. Renewed grants totalling £7,041, for the two years ending 1954, have been made to the Rheumatic Unit, Northern General Hospital, Edinburgh, for continued clinical work with cortisone, studies of cortisone as an adjuvant to the treatment of anaemia in rheumatoid arthritis and other fundamental work. Renewed grants have also been made to the Orthopaedic and Accident Department, London Hospital, to enable Mr. A. Law to continue his studies of surgical treatment in rheumatic disease of the hip, spine and knee, to the Postgraduate Medical School, University of London, for the retrospective follow-up of patients, and to the South-west and Oxford Regional Research Unit, Bath, for completing therapeutic trials of X-ray therapy in osteoarthritis, rheumatoid arthritis, and spondylitis, and of intra-articular injections in osteoarthritis.

New grants for research overseas within the Commonwealth include those to the Waite Agricultural Research Institute, University of Adelaide, to enable Dr. H. L. Penman, of Rothamsted Experimental Station, to visit Australia in connexion with work on evaporation; for Dr. D. F. Thomson, of the Department of Anthropology, University of Melbourne, to visit social anthropologists in the United Kingdom and later to revisit Arnhem Land; to the Department of Chemistry, University of Western Australia, for equipment and infra-red spectroscopical research on Australian natural products; to the University of Otago, for studies in the Department of Botany of morphology and chromosome numbers in *Ranunculus* and transplantation experiments and population analyses, at the Portobello Marine Biological Station, of the physiological mechanisms of animal behaviour and the interpretation of their structure in these terms, and, in the Department of Zoology, of the processes of bird-life. Grants have also been made to the University of Pretoria for work at the Plant Physiological Research Institute on nitrogen assimilation and metabolism in leguminous plants; to the Research Department of Ichthyology, Rhodes University, for research on freshwater fishes of southern Africa; to the Transvaal Museum, Pretoria, for completing the excavations at Swartkrans; and to the Bernard Price Institute of Geophysical Research, University of the Witwatersrand, for the establishment of a Nuffield Geochemical Unit.

For the second year's selection, applications for biological scholarships and bursaries have been stronger in number and quality, and out of thirty eligible applicants, two were awarded scholarships and one a bursary; two sociological scholarships and one bursary were also awarded to the twenty-two applicants under that scheme. The Foundation has reviewed the scheme of travelling scholarships for farmers of the United Kingdom, and reports from the National Farmers' Union suggest that the objects of the scheme are being achieved: ten awards, among sixty-four applicants, were made in 1951. Two travelling fellowships for Home Civil Servants, one in the administrative and one in the professional grade, were made in the year. Only six applications were made for dental fellowships, and three awards were made. Three medical fellowships were awarded among sixteen applicants.

Among new grants for miscellaneous projects may be mentioned one of £3,000 for the compilation of an archive of the Smuts papers and £15,000 towards the inter-congress meetings of the Association of Universities of the British Commonwealth; £650 to the British Committee for Flame Radiation Research to enable a British physicist to work at the Stockholm Technical College's water-cooled plant with heat-absorbing walls; to the British Sociological Association for its first three years, and to Dr. H. Lehmann, of the Department of Pathology, St. Bartholomew's Hospital, for investigations of the blood of south Indian aboriginal tribes, which seem to show that the sickle-cell trait connects the Veddians with Africa although their *Rhesus* blood-groups point to connexion with Australia. A grant of £1,580 to the University of Reading will enable Miss M. D. Vernon, of the Department of Psychology, to direct a three-year study of visual methods in teaching. New grants in continuation of past programmes include a final grant of £4,500 to the Joint Committee of the Royal College of Obstetricians and Gynaecologists, the Population Investigation Committee and the Institute of Child Health, for completing and publishing a report on the study of growth, health and environment of a sample of children from birth to the first year of school life; of £18,000 to the University of Cambridge for the work at the Psychological Laboratory on the problems of ageing, and of £600 for three years to Mr. F. Le Gros Clark for investigations on the social influences that determine retirement, and the employment of ageing persons, and on the capacity of industry, to absorb the labour of ageing persons.

SEISMIC REFRACTION EXPERIMENTS IN THE PACIFIC

By DR. T. F. GASKELL and J. C. SWALLOW
H.M.S. *Challenger*

THIS communication summarizes the results of seismic refraction experiments carried out in H.M.S. *Challenger* in the Pacific during the period October 1950–April 1952. Sixteen stations have been occupied in this area; their positions, and those of the Atlantic stations already described[1], are shown on the accompanying chart. The observed structures fit into five groups, described below.

(1) *Deep ocean types.* Four stations showed a sea bed consisting of a comparatively thin layer of sediment overlying material with a high velocity for compressional sound waves (20,500 ft./sec.). The velocity of sound in the sediment layer was not observed at these stations, but from other measurements is taken to be between 6,000 and 8,000 ft./sec. (Table *A*).

Reverse shots at stations 8, 10 and 11 showed that there was no appreciable slope under the hydrophones. There was no reverse shot at station 17, but the results from successive shots suggest that there may be a small slope, which would give a true velocity of 21,000 ft./sec., and a few hundred feet increase in sediment thickness.

(2) *Deep ocean near islands.* Two stations, one near the Hawaiian islands, the other twenty miles from Funafuti, showed a thin layer of sediment, followed by several thousand feet of material with a sound-velocity of 11,000–15,000 ft./sec. overlying the high-velocity layer (Table *B*).

At station 9, a reverse shot confirmed the 13,500 ft./sec. velocity, but at neither station were reverse points obtained from the high-velocity layer.

Allowing for the remaining possibility of a dip in this layer, the observed velocities are not incompatible with the previous value of 20,500 ft./sec. Adopting this velocity would change the thickness of covering material by only a few hundred feet.

(3) *Western Pacific.* Two stations in deep water, south-west of Formosa, showed a lower sound-velocity for the main layer, with about 2,000 ft. of sediment cover (Table *C*).

The depth of the sea bed was variable; but several reverse shots were made and corrections applied for dip under the hydrophones.

(4) *'Continental' types.* The results at stations 6 and 7, off the North American coast, were not checked by reverse shots, and were obtained over an irregular sea bed. However, two distinct layers are indicated at each station, and the velocity of sound in the deeper layer is substantially less than the 20,500 ft./sec. of the deep Pacific stations. Stations 14 and 15 show a velocity of about 17,000 ft./sec., confirmed by reverse shots (Table *D*).

At station 15, an increase of velocity with depth in the sediment layer was observed, from about 5,000 ft./sec. to 8,300 ft./sec., the latter layer probably being consolidated sediment.

(5) *Near deep trenches.* Stations 13 and 18 were in the deep trench south-west of Guam, at 11½ N., 142¼ E. Some indication of a layer with very high velocity (27,000 ft./sec.) was obtained, but the results were rendered uncertain by drift of the hydrophones over a very irregular sea bed, and by the weakness of the ground waves obtained in these great depths

Table *A*

Station	Position	Depth (fm.)	Velocity in main layer (ft./sec.)	Sediment thickness (ft.)
8	35 N., 143 W.	2,880–2,940	20,900 ± 400	700–1,000
10	26 N., 164½ W.	2,560–2,610	20,300 ± 250	1,100–1,500
11	43½ N., 153 E.	2,770–2,860	20,800 ± 230	2,400–3,400
17	4 N., 146 E.	2,390–2,410	20,100 ± 400	2,100–2,900

Table *C*

Station	Position	Depth (fm.)	Velocity (ft./sec.)	Sediment thickness (ft.)
20	21 N., 127 E.	2,850–3,090	19,100 ± 1,400	1,500–2,100
21	20½ N., 124½ E.	3,030–3,170	18,800 ± 500	2,000–2,800

Table *B*

Station	Position	Depth (fm.)	Velocity in upper layer (ft./sec.)	Velocity in deep layer (ft./sec.)	Sediment thickness (ft.)	Cover material thickness (ft.)
9	22½ N., 160 W.	2,500–2,560	13,500 ± 200	23,000 ± 200	*c.* 100	9,300
16	9 S., 179 E.	2,660–2,690	11,000–15,000	22,200 ± 700	700–1,000	4,500–6,000

Table *D*

Station	Position	Depth (fm.)	Velocity in upper layer (ft./sec.)	Velocity in deep layer (ft./sec.)	Sediment thickness (ft.)	Upper layer thickness (ft.)
6	27½ N., 117 W.	1,830–2,290	10,800	17,200 ± 900	—	0–1,500
7	31 N., 117½ W.	970–1,120	> 9,000	19,400 ± 2,000	700–1,000	*c.* 5,000
14	8½ N., 143 E.	1,230–1,450	—	16,600 ± 200	1,700–2,300	—
15	18 S., 161½ E.	1,540–1,610	8,300	17,700 ± 300	1,100	7,900

Table *E*

Station	Position	Depth (fm.)	Velocity in upper layer (ft./sec.)	Velocity in deep layer (ft./sec.)	Sediment thickness (ft.)	Upper layer thickness (ft.)
12	14½ N., 141 E.	2,650–2,675	19,800 ± 1,100	28,000 ± 900	4,000–5,000	10,000
19	14¾ N., 141 E.	2,630–2,680	20,000 ± 2,300	27,600 ± 800	1,200–1,600	10,000

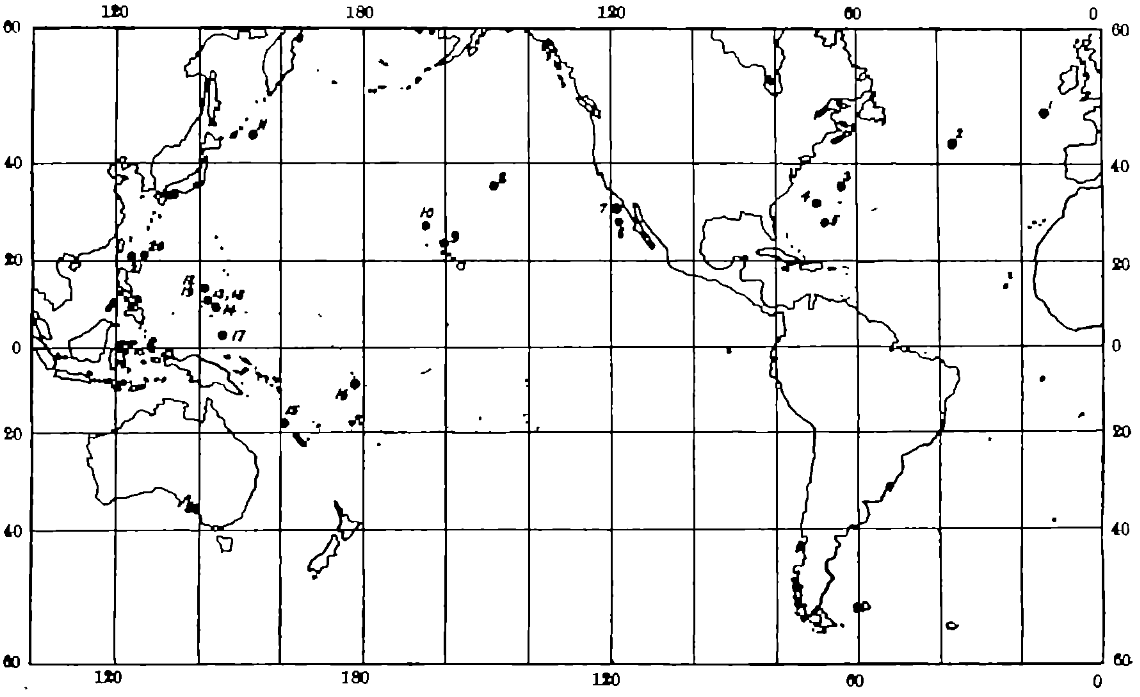
from the small explosive charges available. Station 12, and a repeat station in the same area (19), on the north side of the trench, were interesting in showing a very high velocity, comparatively near the surface (Table *E*).

At station 12, the very high velocity was not checked by a reverse shot, but is supported by the absence of any indication of dip along the direct line. The high velocity of station 19 is derived from shots between 12 and 16 miles from the hydrophones, in both directions.

The main part of the North Pacific basin may well consist of material showing a velocity of sound of 20,500 ft./sec. (probably gabbro or basalt) at least 8,000 ft. thick, covered by one or two thousand feet of sediment. Elevations of the ocean bed are characterized by a lower sound velocity, in the neighbourhood of 13,000 ft./sec., and such material was also observed in experiments on atolls (to be published separately). This probably corresponds to erupted volcanic rock, though it is possible for limestone to show such a velocity. There is evidence at both stations 9 and 16 that subsidence of the deep layer has occurred, due perhaps to the weight of volcanic material resting upon it.

An experiment in shallow water at Ominato in northern Japan showed material with a velocity of sound of 21,600 ft./sec. overlaid by about 6,000 ft. of sediment in which the velocity of sound was 6,400 ft./sec. The high velocity observed is in agreement with recent seismological observations in the same area, showing little, if any, thickness of granite.

The velocity of sound observed for the main layers at stations 20 and 21 is appreciably lower than that



found in the main Pacific basin, and may indicate the presence of a 'granitic layer' in this area, though 19,000 ft./sec. is a rather high velocity for granite. Its thickness would be at least 12,000 ft. assuming 25,000 ft./sec. for the next layer.

The very high velocity observed at stations 12 and 19 is similar to that assigned by seismologists to the layer below the Mohorovičić discontinuity. In the present case, this layer is only 11,000–15,000 ft. below the sea bed.

Station 15 was very similar to the Atlantic stations described by Hill and Swallow[2]. The increase of velocity with depth in the sediment observed at this station may have been present at others, though obscured by irregular topography and the greater depth of water. On the other hand, it may be a property of areas where large thicknesses of sediment have been laid down. The velocity of 17,700 ft./sec. obtained here is probably from a granite layer, and its thickness would be at least 7,500 ft.

These experiments could not have been made without the continuing assistance and co-operation of all on board H.M.S. *Challenger*, or without the support of the Hydrographer of the Navy, and of the Ministry of Supply. [June 19.

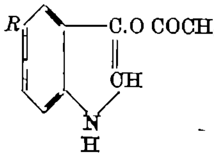
CYTOCHEMICAL LOCALIZATION OF ESTERASES USING INDOXYL DERIVATIVES

By DR. S. J. HOLT and R. F. J. WITHERS

Courtauld Institute of Biochemistry and Biology Department, Middlesex Hospital Medical School, London, W.1

IN response to many requests for further details of a new method for the localization of hydrolytic enzymes in tissues using indoxyl derivatives[1], it is felt that a further brief report is desirable before publication of a more extensive critical account. With derivatives of indoxyl itself, for example, (I, R = H), as enzyme substrates, a major drawback is that the indigo deposit formed by aerial oxidation of enzymically liberated indoxyl is granular or crystalline[1,2], with a particle size comparable to that of various cell structures. Accurate localization of enzymic activity is therefore difficult to determine, since one cannot readily distinguish between dye granules and dyed cell components, apart from other possible sources of error, such as diffusion of dye, chemical precursors of dye, or of enzyme. The factors controlling the size of the indigo crystals have been investigated and undesirable features eliminated as a result of systematic synthetic modifications of the indoxyl molecules as suggested earlier[1]. For this development, the chemically more accessible O-acetyl derivatives of indoxyl, having different substituents in the benzene moiety of the molecule, were studied. Like the parent compound (R = H), these were also found to be rapidly hydrolysed by the common carboxylic acid esterases.

Since the oxidative dye-producing reaction occurs after enzymic hydrolysis, the same indoxyl would be liberated from appropriate derived substrates by different enzymes[1]. The subsequent dye-forming reaction would therefore be the same for each enzyme.



(I)

The different indoxyl acetates thus served not only as simple models on which to study the general effects of chemical substitution on the nature of enzymically produced indigoid dyes, but also to investigate the localization of esterases in tissues. Of a large number of such compounds synthesized for this study[3], 5-bromoindoxyl acetate (I, R = Br) was found to be a satisfactory compromise between ease of preparation, tinctorial power and size of particles of the derived dye (5 : 5′-dibromoindigo). This rich blue, extremely insoluble dye was found to form a deposit so free from granularity that no particles could be detected in suitably homogeneous tissue sites (for example, contents of pancreatic duct) under the highest powers of the optical microscope plus photographic enlargement. In most other sites, granules, when produced, were far smaller than the common cell organelles (excluding microsomes). Only in the presence of gross lipoid (for example, fat cells) having esterase activity[4] did recognizable crystals appear, but even here these were much smaller than with the unsubstituted compound. Such sites could easily be distinguished, however, by carrying out control experiments with fat dyes such as Sudan IV.

The possibility of developing a method for the intracellular localization of esterases thus appeared to be possible, provided that the substrate penetrated to all cytological levels (see below), that the dye produced stained the cell organelles possessing esterase activity and that diffusion effects could be controlled. This was not immediately feasible, however, for several reasons. First, the indoxyl acetates failed to indicate, or only very inadequately so, the presence of esterases in certain sites of known high activity, for example, the motor end-plates of striated muscle. Here, a very diffuse staining reaction took place in both fresh and formalin-fixed frozen sections. This was traced to the rapid diffusion of the enzymically liberated indoxyl away from the site of generation into the surrounding tissue and substrate solution before complete oxidation to the corresponding indigo could take place. Such diffusion was intrinsically much less with the 5-bromo-derivative and with other similarly less soluble, high-molecular weight compounds. In all cases, diffusion was greatly reduced and localization improved by traces (10^{-4} M) of cupric salts, as mentioned previously[1]. This improvement has now been traced to the catalytic effect of the cupric ion in speeding up the oxidation of the enzymically liberated indoxyl.

The process thus seemed open to very much greater control than other histochemical localization procedures, by the use of oxidation catalysts or oxidizing reagents of graded strength, which obviously had to be selected to have as little effect on enzyme activity as possible. It appeared logical to assume that the more rapidly the free indoxyl could be oxidized to the corresponding indigo, the nearer the site of the enzyme would the dye be deposited. This hypothesis was fully borne out by experiment. Of the many oxidizing agents and catalysts tested for inclusion in the substrate solution, potassium ferricyanide appeared to be the most satisfactory, agreeing with similar observations made during a parallel series of investigations by Burgen[6] at McGill University. A tendency for the indigo formed to be bleached by further oxidation to dehydroindigo could be prevented by also adding an equimolar proportion of potassium ferrocyanide. As test objects, in view of their fine and complex structure, the motor end-plates of mouse intercostal muscle and rat diaphragm were used. As the quantity of oxidizing agent was increased from zero to the optimum, the result produced in the muscle tissue, using 5-bromoindoxyl acetate as substrate, changed from the non-localized staining mentioned above, through diffuse circular patches on each muscle fibre, to a sharply delineated structure (Fig. 1) comparable with the results obtained by Couteaux[5] using his Janus green technique.

No further effect could be obtained by increasing the concentration of the oxidizing agent above 5×10^{-3} *M* of each component salt. With formalin-fixed tissues (see below) the motor end-plates already showed staining in as little as 10 sec. Even after 48 hr. incubation, the stained structures were merely very much darker than with the short period, which is a good indication of the specificity of the reaction, absence of autohydrolytic deposition of dye and negligible diffusion effects. With long incubation times, the only difference found was that the nerve supply to the end-plates became lightly stained.

Under optimum conditions, acetylindoxyl still produced a granular diffuse deposit, and we now consider that unsubstituted indoxyl is a poor basis for derived substrates for accurate histochemical localization of esterases.

Direct application of the optimum substrates to many other tissues produced, for the first time, consistent, easily reproducible intracellular localization of esterases. In particular, the results produced with rat kidney and liver were interesting. In the kidney, the sites of esterase activity in the tubular epithelium consisted of intracellular spherical bodies, diameter approximately 1–3 µ (Fig. 2), which, when stained less intensely than illustrated, often showed a concentric spherical structure, only the inner component being stained. In the liver, esterase activity was seen to be mainly associated with particles resembling liver mitochondria in appearance, clustered around the intercellular bile canaliculi (Fig. 3).

Results illustrated were obtained with tissues fixed for 16 hr. in cold (4°) neutral formalin (5 per cent formaldehyde) containing sodium chloride (0·9 per cent). Frozen sections were cut at a thickness of 5 µ and incubated in a substrate solution containing the following concentrations of components: 5-bromoindoxyl acetate ($2 \cdot 5 \times 10^{-4}$ *M*), potassium ferricyanide and potassium ferrocyanide (5×10^{-3} *M* of each), calcium chloride (10^{-2} *M*), 0·1 *M* tris-hydroxymethylaminomethane maleate[7] buffer *p*H 8·0 (2 ml. in 10 ml. of substrate solution). Sections were examined periodically and removed when the stain, which appears spontaneously, was sufficiently intense.

Control experiments showed that none of the blue staining obtained in tissues was due to the presence of iron, which would give a Prussian blue deposit with the ferro-ferricyanide reagent. On the other hand, the use of steel needles to manipulate the tissues often resulted in contamination of this type, although it has not been observed after using steel microtome knives.

The use of fresh-frozen sections is unsatisfactory, for common reducing substances in such tissue quickly destroy the ferricyanide, apart from effects due to diffusion of enzyme.

With the degree of intracellular localization obtained, it soon became obvious that tissues fixed and cut as described above were inadequate for critical cytochemical studies. Apart from the well-known translocation of substances occurring during chemical fixation of fresh tissues[8], the relatively slow freezing at the microtome invariably produced some ice crystal artefacts. At present, frozen-dried tissues are being examined, as these appear to be more suitable for cytological studies[9]. Until results with frozen-dried material are fully evaluated, no claims are made for the accuracy of the cytological localization achieved with formalin-fixed material. The nature of the cell organelles staining by this process is also being studied by a number of complementary staining and optical techniques.

Fig. 3. Rat liver. Esterase activity mainly associated with particles clustered around bile canaliculi. × 650

Non-critical methods for localization of enzymic activity usually show somewhat diffuse activity in tissues, particularly from the cytological point of view. Such methods may also indicate activity at sites known to contain no enzyme or vice versa. Observations of this kind have formed the basis for considerable doubts to be thrown upon the validity of histochemical staining techniques. In our experience, for precise localization, it seems essential that different types of tissue should be studied independently, to arrive at the optimum conditions for each. With the 5-bromoindoxyl acetate method described briefly above, good results are obtained with most tissues, except those of the central nervous system, where very little activity is demonstrable with the substrate solution described. This appears to be associated with the high phospholipin content of such tissues; but the difficulty can be overcome by modifying the ratio of the components of the substrate solution. We are studying this type of problem, but a full investigation of the use of 5-bromoindoxyl acetate with tissues of the central nervous system is being carried out by Burgen.

Apparently, different effects of the type mentioned above, in the action of tissues on enzyme-indicating substrates, are not by any means restricted to the indoxyl method. A typical case is that which arises with more familiar methods for the localization of esterases, such as the myristoylcholine method[10], the naphthyl acetate[11] and thiocholine[12] techniques. In each of these methods, in spite of claims to give good localization of esterase activity, none demonstrates such activity in one of the most important and least to be doubted sites of esterase, namely, the erythrocytes of, say, the rat. This does not even appear to have been specifically mentioned before, and should at once cast doubt on the validity of these methods, unless their scope and limitations have been previously thoroughly investigated, which does not appear to be the case. With the indoxyl method, in the absence of cupric ions or the ferro-ferricyanide mixture, the erythrocyte is one of the major staining sites. In the presence of the oxidizing catalyst or agent, however, the staining reaction is inhibited; this has been traced to the effect of these reagents on the special permeability properties of the erythrocyte membrane. The effect of copper in this connexion is well known[13]. In a subsequent publication it will be shown the failure to stain erythrocytes by the choline fatty acid ester technique is due to the failure of the quaternary ammonium salt substrate to penetrate the red cell envelope. In the naphthyl acetate method, the diazonium ions from the coupling reagent will also be shown not to penetrate the red cell membrane, and in the thiocholine techniques, sufficient copper is present in the substrate solution to destroy the permeability of this membrane. In addition, staining artefacts may well arise from a temporary or permanent fixation of the quaternary cations by acidic components of the tissue. The nuclear staining extensively found when using the thiocholine technique is probably due to such an effect and is being investigated. With substrates derived from indoxyl, chemically and electrically neutral molecules are involved, with which such artefacts should be minimal, and rates of penetration high, and possibly may become still higher as a result of further modifications of the molecular structure at present being developed.

We thank Mr. Peter Runnicles, of the Anatomy Department of this Medical School, for the photomicrographs, and the University of London for a grant to one of us (R. F. J. W.) from the Central Research Fund of the University. [November 6.

PURIFICATION OF CYTOCHROME *C*

By Dr. E. MARGOLIASH*
Molteno Institute, University of Cambridge

THE first preparations of mammalian heart cytochrome *c* had an iron content of 0·34 per cent[1,2]. Theorell and Åkesson[3], however, showed that very prolonged electrophoresis in the large-scale Tiselius apparatus resulted in the separation of a fraction having 0·43 per cent iron. Less cumbersome techniques have been developed since for the production of the 0·43 per cent iron type of preparation[4,5], but they are not very reliable and have involved the use of conditions that cause a considerable reduction in the yield of cytochrome *c*. Paléus and Neilands[6] have used the synthetic polycarboxylic resin 'Amberlite *IRC*-50' for the chromatography of cytochrome *c* at *p*H 9, obtaining several fractions containing up to 0·466 per cent iron. The eluates obtained were very dilute and were concentrated by precipitation with trichloroacetic acid in the cold. My experience has been, however, that this last step causes, in the absence of saturated ammonium sulphate, a very great reduction of the enzymic activity.

Preparation of 0·43 per cent iron cytochrome c. With any suitable cation exchanger, the chromatographic separation of several distinct fractions could be effected from cytochrome *c* containing 0·34 per cent iron, using as eluant any monovalent cation at neutral *p*H and a concentration of 0·25 *M*. The first or colourless non-cytochrome fraction was entirely unadsorbed by the cation exchanger, so that the use of a chromatographic column was unnecessary.

The method finally adopted for the preparation of 0·43 per cent iron horse heart cytochrome *c* was as follows: 'Amberlite *IRC*-50' (The Rohm and Haas Co., Philadelphia, U.S.A.) is ground and the fraction settling in water between 15 sec. and 3 min. collected. It is converted into the ammonium salt using an excess of 2 *N* ammonium hydroxide, and then dried in air between two layers of filter paper until there is no detectable smell of ammonia. 100 ml. of a 1 per cent solution of 0·34 per cent iron cytochrome *c*, prepared from horse hearts by the method of Keilin and Hartree[4], and well dialysed against water, are gently shaken with 15 gm. of the resin until adsorption is complete. The resin is collected on a coarse sintered glass funnel and thoroughly washed with glass-distilled water.

---

* On leave from the Hebrew University, Jerusalem.

The cytochrome *c* is then eluted with several washings of 15 ml. of 0·25 *M* ammonium hydroxide, keeping only the coloured portion of the eluate. The eluate is at once dialysed against running tap-water followed by three to four changes of distilled water, and finally filtered through a retentive filter paper.

The product has an iron content of 0·43 per cent, does not contain any denatured or modified cytochrome *c*, and with careful elution may be obtained in concentrations 1·5–2 times that of the original solution. It was found to be as fully active enzymically as the usual preparations, per mole of iron, in the succinic oxidase and cytochrome oxidase systems, these assays being carried out in Barcroft differential manometers at 37° C. and a *p*H of 7·3 (phosphate buffer), using varying amounts of added cytochrome *c* with cytochrome *c*-deficient enzyme preparations (kidney preparations, according to Slater[7], and heart muscle preparations, according to Tsou[8]) in the test systems given by Slater[7,9].

Repetition of the procedure three times on the same sample did not cause an increase of the iron content above 0·43 per cent. It is possible, however, that chromatography would give a higher iron content. The overall yield was 85–97 per cent.

The advantages of such a method over those previously used are its simplicity and rapidity, its reliability and the fact that the product is obtained directly in a concentrated form with full enzymic activity, the yield being practically quantitative. Moreover, the colourless fraction of the 0·34 per cent iron preparation is separated at its original concentration, giving an excellent starting material for its isolation and identification.

The success of this type of procedure depends on the fact that the isoelectric point of cytochrome *c* is at a *p*H of 10·6, thus making it act as a cation at lower *p*H values, whereas the associated protein substance or substances react as anions. Moreover, the cation exchangers effectively distinguish between native and modified cytochrome *c* in solution, only the native form being adsorbed; indeed, the products of the type of procedure described above show the same degree of reduction enzymically with succinic dehydrogenase as with an excess of sodium hydrosulphite, whereas the usual preparations commonly show a slightly greater degree of reduction chemically than when reduced enzymically.

The ease with which the colourless fraction of the 0·34 per cent iron preparations is separated by cation exchangers makes it reasonable to suppose that the bond between it and the rest of the molecule is a simple ionic one, confirming the electrophoretic observations of Theorell and Åkesson[3].

It should be noted that 'Amberlite *IRC*-50' is by no means the only cation exchanger which can be used, identical results having been obtained, for example, with 'Decalso *F*' (The Permutit Co., Ltd., London), which is an aluminium silicate.

Preparation of reduced or oxidized cytochrome c in a stable form. The simplicity of the procedure for adsorbing and eluting cytochrome *c* from a suitable cation exchanger makes it a very satisfactory method for the preparation of reduced or oxidized cytochrome *c*, free from any extraneous substance.

The techniques which have usually been employed are bubbling hydrogen gas in the presence of platinum black for reduction, which is effective only in rather dilute solution, or the use of chemical agents such as sodium hydrosulphite or ascorbic acid for reduction, and potassium ferricyanide for oxidation, leaving an excess of the reagent and its reaction products in solution.

The procedure using cation exchangers is as follows: 100 ml. of a solution containing 80–120 µmol. of 0·43 per cent iron horse heart cytochrome *c* prepared by the cation exchange method, is reduced with ascorbic acid or fully oxidized with potassium ferricyanide. Freshly prepared solutions are used, adding no more than twice the calculated stoichiometric amounts, the ascorbic acid being neutralized and containing versene (ethylene diamine tetra acetic acid) to stop its auto-oxidation.

The solution is then shaken with 20 gm. of the ammonium or potassium salt of 'Amberlite *IRC*-50, depending on the subsequent elution, per 100 µmol. of cytochrome *c*, until adsorption is complete; the resin is prepared as given above for the ammonium salt.

The cation exchanger carrying the reduced or oxidized cytochrome *c* is quickly collected on a coarse sintered glass funnel, thoroughly washed with glass-distilled water and sucked dry.

When oxidized cytochrome *c* is desired, the protein can be eluted as described above with 0·25 *M* ammonium hydroxide, filtered and immediately freeze-dried over sulphuric acid and sodium hydroxide.

When reduced cytochrome *c* is being prepared, it is necessary to avoid the alkaline *p*H's at which cytochrome *c* begins to be auto-oxidizable, and the elution is carried out with four to six washings of 20 ml. of 0·25 *M* potassium chloride. The eluate is dialysed for 5–6 hr. in the cold, with shaking, against running distilled water, filtered and freeze-dried.

The products are powdered and kept in ampoules sealed *in vacuo*. After storage at 0° C., the powders dissolve to give clear solutions having substantially the same percentage reduced or oxidized cytochrome *c* as when prepared, and showing full enzymic activity.

The advantages of this method over those hitherto used are the stability of the dried product in the reduced or oxidized form, the possibility of obtaining reduced or oxidized cytochrome *c* in a solution of any desired strength, and the complete freedom from the chemical agents used for reduction or oxidation and the reaction products. Such a product is particularly useful when it is necessary in enzymic studies to use cytochrome *c* in stoichiometric rather than catalytic quantities.

A detailed report of these techniques and their results will be published elsewhere. I wish to express my gratitude to Prof. D. Keilin for his constant advice and encouragement during this work. Thanks are also due to Dr. E. C. Slater for his advice in enzymatic matters, and to Mr. N. K. Boardman and Dr. S. M. Partridge for their help in the use of ion-exchangers. [Aug. 6.

Note added in proof. Neilands[10] now uses saturated ammonium acetate for elution from a column of 'Amberlite *IRC*-50', and obtains an enzymically active cytochrome *c*.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Resistance to the Potato Root Eelworm, *Heterodera rostochiensis* Wollenweber

I have already reported some of the results of my search for resistance to the potato root eelworm among the South American tuber-forming *Solanum* species in the Commonwealth Potato Collection[1,2]. This work, begun in 1941, is now practically complete, and more than 1,200 lines, belonging to more than sixty species, have been tested in duplicate on at least one occasion. Very few have been found to be resistant; one such line, *Solanum ballsii*, has certain disadvantages for breeding work as it is a diploid, whereas the domestic potato, *S. tuberosum*, is a tetraploid. In 1948, however, I was fortunate in finding a further five apparently resistant lines (C.P.S. numbers, 1673. 1685, 1692, 1595 and 1647), four of which belong to *S. tuberosum* sub-species *andigenum*, a group of tetraploids very close to the domestic potato and readily crossed with it; the other (1647) is a sterile triploid. Tests in later years have confirmed the early promise of these lines.

The routine tests to which all lines are subjected is of a very simple sort. The plants are grown in duplicate in pots of infested soil sunk in the soil of an infested allotment. At the end of the season, the plants are lifted and their roots examined for cysts. Promising lines are selected for further test if they have few cysts on their roots; but as this may be the case for a variety of reasons, factors such as the vigour of the plant and the extent and type of root system, etc., are also taken into account. Such an assessment, clearly, is of a subjective nature, and even though the evidence of repeat tests on a larger scale may reinforce a first impression, there is no evidence, as I have already pointed out[2,3], that the assessment is sound and the apparent resistance not the result, from the present point of view, of secondary factors. However, this possibility can be tested, for, by appropriate sexual and vegetative propagation, it is possible to compare a series of genetically different clones of common parentage and of very similar general habit; the results of such experiments are now available.

In 1951, Dr. K. S. Dodds, of the Potato Genetics Station, Cambridge, which houses the potato collection, supplied Dr. H. J. Toxopeus, of Wageningen, with selfed seed of three of the lines of *andigenum* first found by me in 1948 to be probably resistant. Some of his results are reported in the accompanying communication, and it is gratifying to find that they provide strong evidence that resistance to the potato root eelworm is probably inherited. The resistance of the four *andigenum* lines likely to be useful in potato breeding is now being examined on a much larger scale, both in Holland and in England.

Genotypical Background of Resistance to *Heterodera rostochiensis* in *Solanum tuberosum*, var. *andigenum*

In January 1951, we received from the Potato Genetics Station at Cambridge some selfed seed of three clones of *S. tuberosum* subspecies *andigenum* which, according to the experiments of Dr. C. Ellenby, seemed as if they might serve as a basis for breeding for resistance to potato root eelworm, *Heterodera rostochiensis*.

The seeds were sown immediately, and in April five to ten cuttings were made from each of the seedlings. These cuttings were transplanted into 7-in. pots filled with sandy soil heavily infested with potato root eelworm. The pots were embedded at random in the field and several rows of pots containing the domestic variety Eigenheimer were used as controls.

Six weeks after transplanting, yellow cysts could easily be seen on the roots of susceptible plants when they were removed from the pots. It appeared that all plants of a clone were either free or nearly free from cysts, or as heavily infected as the domestic controls. The results of the inspection are given in Table 1.

Table 1. Infection of *andigenum* Seedlings with Potato Root Eelworm

Parent	Number of clones Without cysts	With many cysts
C.P.C. 1673	16	4
C.P.C. 1685	7	3
C.P.C. 1692	2	0

When the plants had finished growing, 20-c.c. samples of soil were taken from some of the pots and the number of cysts in each of these samples was determined. The results are given in Table 2.

Table 2. Counts of Cysts and Larvae in 20-c.c. Samples of Soil

Material	Cysts	Viable cysts	Larvae	Number of Pots	Clones
S. tuberosum	58 ± 6·5	47 ± 5·4	4,300 ± 635	10	–
S. andigenum susceptible	55 ± 5·2	43 ± 4·9	3,600 ± 475	18	4
S. andigenum resistant	11 ± 1·0	2	30	21	8
Initial potting soil	18 ± 3·0	5 ± 1	250 ± 75		

It will be seen that twenty-five seedlings were apparently resistant to infection and that seven were susceptible. In the pots containing the domestic variety and the susceptible seedlings of *andigenum*, the number of viable cysts increased nearly ninefold, whereas, in the pots containing the resistant seedlings of *andigenum*, the population of cysts did not increase. These results suggest that resistance to potato root eelworm is inherited; but the progenies used were too small to permit an interpretation of the genetic mechanism involved.

S. tuberosum subspecies *andigenum* is cultivated in the Andean regions from Venezuela to northern Argentina, and apparently is closely related to domestic varieties, which represent only a small part of this very variable species. For this reason resistant *andigenum* varieties would seem to offer a very good basis for a practical breeding programme, and their possibilities are now being examined on a much wider scale.

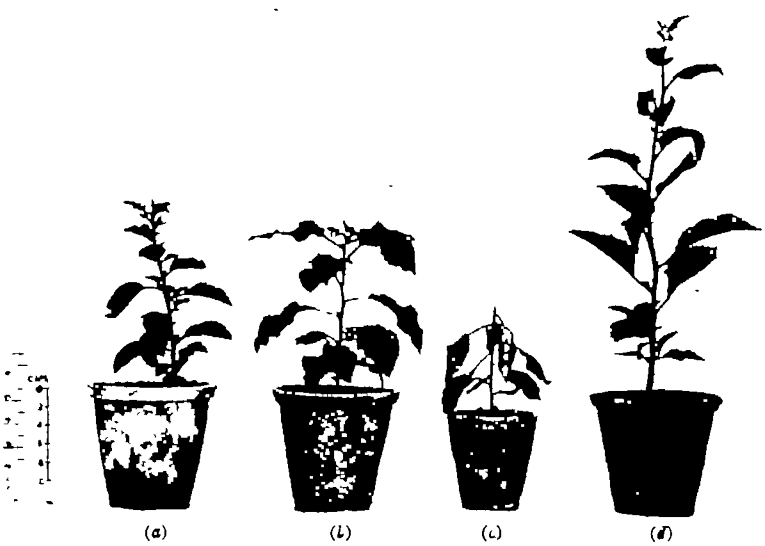
Pear-Apple Hybrids

At the John Innes Horticultural Institution we have recently raised hybrids between pears and apples; they were obtained in the following way. The occurrence of apomixis in the Pomoideæ[1], and the high frequency of diploid seedlings, 23 out of 39, in a family of pears we raised from crossing the diploid variety Fertility with the triploid variety Beurre Diel, suggested that they may have been apomictically, or in part apomictically, reproduced. To test this possibility one of us (E. M.) isolated a tree of Fertility, emasculated sixteen flowers and brushed the ovaries over with a 40 p.p.m. solution of β-naphthoxy-acetic acid. Four flowers were pollinated with the pollen of an unnamed tetraploid variety of apple and twelve with the pollen of the diploid apple Crawley Beauty. Twenty-four hours later the ovaries were again treated with β-naphthoxy-acetic acid. Three fruits developed from pollination with the tetraploid apple and twelve from pollination with the diploid. Seed content and germination are shown in the following table.



(a) Pear, (b) surviving pear–apple hybrid, (c) dying pear–apple hybrid, (d) apple

Pear	Fertility 2x	Flowers	Fruit	Seeds	Seeds sown	Germinated	Survived
×	Apple 4x	4	3	18	18	13	1
×	Apple 2x	12	12	100	79	56	10

During the early stages of growth the seedlings were very uniform, and at first we thought they were pears of apomictic origin. Later their development was unusual, and it became clear that the plants were not pear seedlings but pear–apple hybrids. They developed intermediate characters, and after three months showed slightly greater resemblance to the male apple parent, though distinct from normal apple. Furthermore, all the seedlings had a somewhat defective root development and appeared to lack ability to take up sufficient of some of the essential mineral nutrients. In consequence, many of the seedlings died, but eleven have survived (see table and photograph). From preliminary grafting of some of the hybrids on to apple seedlings, it appears that difficulty in growth may be overcome.

One seedling in each family has been examined cytologically by Mr. R. D. Brock: the one in which the tetraploid apple was the male parent was triploid and the one with the diploid apple parent was diploid. This supports their hybridity.

In the past we have made pollinations between apples and pears but never obtained seeds. They were made without any hormone treatment, and it therefore seems that, when distant crosses with plants are being attempted, the use of β-naphthoxy-acetic acid may be of value.

It appears that this is the first time sexual hybrids between pears and apples have been produced. In *Plant Breeding Extracts*[2], an apple pear hybrid is referred to in Sweden, at the Balsgård Fruit Breeding Institute; but Dr. I. Granhall, director of the Institute, has recently informed us that this is wrong and that no such hybrid is known in Sweden. According to Dr. Granhall, this false report originally appeared in a newspaper article. The alleged apple pear vegetative hybrid Renette-Bergamotte, referred to so much in recent years by Soviet scientific men, is figured, and an account of it given, in Michurin's "Selected Works". From the illustrations and the descriptive account of Renette–Bergamotte, it appears to us to be entirely apple.

Rate of Photosynthesis and Concentration of Carbon Dioxide in *Chlorella*

Previous investigations of the relationship in *Chlorella* between rate of photosynthesis at high light intensities and concentration of carbon dioxide have been made using cells suspended in alkaline solutions[1]. In such solutions cells grown in 4 per cent carbon dioxide show an unusually long induction phase ($t_{1/2}$, 40–50 min.) at low concentrations of carbon dioxide; but when allowance is made for this and the rate of photosynthesis in the steady state alone considered, half the maximum rate is attained with a concentration of carbon dioxide[2] of 0·9 × 10^{-6} *M* at 25° C. The possibility has been suggested that in alkaline solution the relatively high concentration of bicarbonate ion affects the rate of photosynthesis[3].

Experiments have now been made with *Chlorella pyrenoidosa* in acid phosphate solution (*M*/30 potassium dihydrogen phosphate, *p*H 4·6). The cell suspension was placed in a tube containing a sintered glass bubbler which was connected in a closed circuit with appropriate drying tubes and with one absorption tube of the infra-red gas analyser manufactured by Grubb Parsons. The control tube contained carbon dioxide-free air. Within the closed circuit a hermetically sealed pump continuously circulated the gas so that a complete cycle was achieved every 10–15 sec. The apparatus was calibrated by adding standard carbonate from a burette to acid contained in the bubbling tube, thus giving an absolute calibration as well as a measure of the response time of the system.

When *Chlorella* is placed in the bubbler tube and illuminated, the concentration of carbon dioxide progressively falls, and from the time-course the relationship between the rate of removal of carbon dioxide from the gas phase and the concentration in the gas phase can be determined. It can be shown that the actual rate of photosynthesis is greater than the measured rate, and that the concentration of carbon dioxide in the gas phase is greater than that in equilibrium with the aqueous phase in the cells. Thus any estimate of the concentration of carbon dioxide for half maximal rate of photosynthesis made from such observations must be maximal. Results are shown in the accompanying table. From the linear portion of a graph of the reciprocal of the rate against the reciprocal concentration, an estimate of the minimum concentration to give half the maximal extrapolated rate is $1\cdot20 \times 10^{-6}$ *M* (that is, allowing for solubility of the gas, $0\cdot95 \times 10^{-6}$ *M* in solution) at 25° C. This is in good agreement with our earlier measurements in alkaline solution; further, aliquots of cells from the same culture gave the same value using either method. Similar experiments with *Chlorella vulgaris* have been described by Egle (a report of which was not seen, however, until after the completion of this work), and his results are consistent with our own[4]. In the present measurements any possible role of bicarbonate ion is excluded since the concentration in solution at *p*H 4·6 is negligible.

RELATIONSHIP BETWEEN RATE OF PHOTOSYNTHESIS AND CONCENTRATION OF CARBON DIOXIDE IN *Chlorella pyrenoidosa*

Concentration of carbon dioxide (%)	0·0300	0·0108	0·0089	0·0070	0·0052	0·0033	0·0017	0·0013
Rate of real photosynthesis	18·0	16·8	16·3	14·6	12·9	11·5	8·5	6·8

The rate was determined after 40 min. illumination, that is, after the induction phase was ended. It is expressed as µl./µl. cells/hr. Concentration is in volume per cent at 760 mm. pressure. Temperature 25° C.; light intensity, 20,000 lux.; *p*H 4·6.

Both at *p*H 4·6 and 6·8 a long induction phase was observed at a concentration of carbon dioxide maintained between 0·01 and 0·02 per cent; but it was shorter the more acid the solution ($t_{\frac{1}{2}}$, 13 min. at *p*H 4·6; 18 min. at *p*H 6·8). At *p*H 6·8 and 8·2, preliminary experiments indicate that higher concentrations of carbon dioxide are necessary for half saturation.

A fuller discussion of these observations will appear in a joint paper with Prof. G. E. Briggs, to whom I am grateful for helpful advice. I also wish to thank the Agricultural Research Council for financial assistance.

Chemical Differentiation of the Genera *Podocarpus* and *Dacrydium*

THERE are numerous instances where a genus or other group of plants is characterized by particular chemical constituents. In the Eucalypts, for example, chemical evidence has been of value in some instances in determining specific differences, while in *Pinus*, Erdtman and co-workers[1] have recently shown the presence of a characteristic pattern of heartwood constituents.

From the results of a study of rimu (*Dacrydium cupressinum*) we have been led to consider the data available in the Podocarpaceae. A clear distinction between the genera *Podocarpus* and *Dacrydium* is apparent, with the interesting exception of *D. cupressinum*.

In various species of *Podocarpus* and *Dacrydium*, the heart-shake resin, the oleo-resin and the resin extracted with solvents from the wood have been investigated and found to consist principally of oxygenated diterpenoids. They fall into the following two distinct groups:

(*a*) Phenolic tricyclic diterpenes, namely, ferruginol from the oleo-resin of *P. ferrugineus*, totarol and a small amount of what is probably a hydroxy totarol[3] from the wood resin of *P. totara*, ferruginol 9-keto-ferruginol and totarol from the wood resin of *D. cupressinum*[2]. This wood also contains as the heart-shake resin podocarpic acid. The same heart-shake resin occurs in *P. dacrydioides* and in the Javanese species *P. cupressinus*.

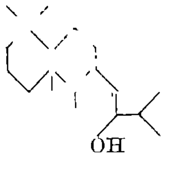
(*b*) Non-phenolic diterpenoids with two carbocyclic rings, namely, manool from *D. biforme*, *D. bidwillii*[4] and *D. kirkii*, manoyl oxide, 3-ketomanoyl oxide and a trihydroxyditerpene oxide from *D. colensoi*. These substances are all obtained by solvent extraction of the wood.

It should be pointed out that in *Podocarpus* the solvent-extractable resin has only been investigated in *P. totara* and *P. dacrydioides*[5]. The latter wood contains relatively little resin and the manool type of diterpenoid appears to be absent. *P. spicatus* gives a heart-shake resin containing the structurally unrelated matairesinol and conidendrin, but the solvent extract has not been studied. A summary of the diterpenoids of the resins of the *Podocarpus* and *Dacrydium* genera is set out in the accompanying table.

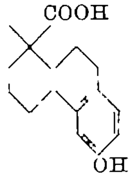
On the chemical evidence available, it appears that *D. cupressinum* shows much less affinity with

CONSTITUENTS OF THE WOODS OF *Podocarpus* AND *Dacrydium*

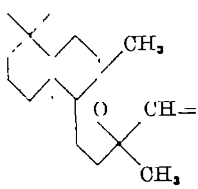
Wood	Constituents	Chemical type
Podocarpus ferrugineus	Ferruginol	Tricyclic phenolic diterpenes or related thereto
P. totara	Totarol, hydroxytotarol (?)	
P. dacrydioides	Podocarpic acid	
P. cupressinus	Podocarpic acid	
Dacrydium cupressinum	Podocarpic acid, totarol, ferruginol, and 9-keto-ferruginol	
D. biforme	Manool	Bicyclic oxygenated diterpenes (non-phenolic)
D. kirkii	Manool	
D. bidwillii	Manool	
D. colensoi	Manoyl oxide, 3-ketomanoyl oxide, a trihydroxy-diterpene oxide	



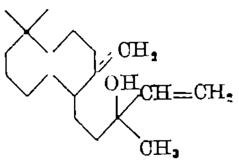
Ferruginol



Podocarpic acid



Manoyl oxide



Manool

Dacrydium, but a close relationship to, and should perhaps be placed with, *Podocarpus*. This conclusion is in agreement with the view that the anatomical features of the wood resemble those of *Podocarpus*[6].

Early Effects of Growth Substances

ISOLATED cambium-phloem strips from *Bryophyllum calycinum* Salisb. show a curvature with the cambium at the concave surface, and this curvature is increased when the strips are placed in water. Plasmolysis causes the complete relaxation of the strip. Partial relaxation can be obtained in solutions of indolylacetic acid and 2,4-dichlorophenoxyacetic acid (2,4-D) in concentrations of 1-50 parts per million, the action of indolylacetic acid being in some cases reversible. It can be shown that the average width of the cambium cells decreases immediately after placing the strip in the hormone solution. The reaction is strongly influenced by temperature; it occurs between 15° and 30° C., with an optimum near 30° C. At 29° C. a maximal curvature of the strip (or shrinkage of the cambium cells) is obtained within five minutes. In indolylacetic acid, 1 20 p.p.m., a reversal of this shrinkage occurs which may lead to an increase beyond the original size of the cell; this might properly be considered as growth. At 29° C. the reversal appears twenty minutes after the beginning of the experiment.

Similar almost instantaneous effects of growth substances were demonstrated on the nyctinastic movements of various *Oxalis* spp., in which 2,4-dichlorophenoxyacetic acid, 1-100 p.p.m., and also indolylacetic acid cause a suppression, or even reversal, of the normal movement of the leaflets. This effect, too, may be accounted for by a sudden change of turgor, in this case in the pulvinar cells.

With *Bryophyllum* and carrot tissue, preliminary experiments have shown that 2,4-dichlorophenoxyacetic acid (1-50 p.p.m.) does not increase permeability to neutral red or ammonium ions. Plasmolysis in hypertonic glucose, as well as in glycerol, is materially accelerated in 2,4-dichlorophenoxyacetic acid, even in concentrations as low as one part in ten million.

We have also observed the disappearance of air from the intercellularies after treatment with 2,4-dichlorophenoxyacetic acid. This phenomenon, caused by an extrusion of water or cell sap, had been observed already in 1930 by Miss Nicolai[1] using cress roots mechanically stimulated at certain spots; at these spots the roots developed nodules. It is possible that the production of swellings by 2,4-dichlorophenoxyacetic acid, as well as the internal wilt which appears after its application, may yet be traced to the same cause, namely, an initial loss of water or sap from the cell.

The experimental work will be published in the near future. This research has been made possible by a grant from Timbrol Pty., Ltd., Australia.

Corchsularin, a New Bitter Principle from Jute Seeds (*Corchorus capsularis*, Linn.)

SEN isolated corchorin[1], a crystalline bitter principle of melting point 174° C. and molecular composition $C_{22}H_{36}O_8$ and corchoritin[2], having melting point 218–222° C. and molecular formula $C_{15}H_{18}O_5$ from the alcoholic extract of jute seeds (*Corchorus capsularis*, Linn.). Karrer and Banerjee[3] obtained corchortoxin, having melting point 247° C. and molecular composition $C_{23}H_{32}O_6$. Soliman and Saleh[4] identified corchorin as strophanthidin.

We are also engaged upon a study of the bitter principles of jute seeds. Simply by extracting jute seeds with rectified spirit and digesting the alcohol-free extract with boiling water, a better yield of corchorin has been obtained. Corchorin extracted in this manner agrees largely as regards properties with those described by Sen and fails to show its identity with strophanthidin. It has also been found that a new bitter accompanies corchorin. This has been isolated and crystallized. It has a melting point of 157° C. and molecular composition $C_{29}H_{47}O_9$. Since this is neither corchorin, corchoritin nor corchortoxin, we propose a new name, 'corchsularin', for the substance. Corchsularin yields, on acid-hydrolysis, a new deoxy sugar, for which we also propose the name 'corchsularose'. Corchsularose has been found to be a deoxy methyl pentose.

A fuller account of this work will be published elsewhere.

Identity of *Polystictus* (= *Polyporus* = *Trametes*) *cinnabarinus* (Jacq.) Fr. with *Polystictus sanguineus* (L.) Fr.

Externally, sporophores of the two species, *Polystictus cinnabarinus* and *P. sanguineus*, differ in the tint of red coloration and in the nature of the porous areas, though they are regarded by many as identical. Miss Wakefield holds (personal communication, 1948) *Polystictus sanguineus* as the tropical country-analogue of *Polystictus* (*Trametes*) *cinnabarinus* of the temperate climate. Cunningham[1], in his recent revision of Australian Polyporaceae in herbaria of the Royal Botanic Gardens, Kew, and of the British Museum (Natural History), holds *Polyporus* (*Coriolus*) *sanguineus* Fr. to be identical with *Polyporus cinnabarinus* Fr., with the remark that "there is no constant feature upon which two species may be maintained". Cleland[2] is also of the same opinion, as he noticed fruit bodies of *Polystictus sanguineus* and *Polyporus cinnabarinus* growing in the same area of Sydney, almost at any time of the year after sufficient rain, on fallen logs. Lloyd[3] holds *Polystictus cinnabarinus* as the temperate region-analogue of the tropical *Polystictus sanguineus*.

Cultural characters of the two species in malt extract–agar slants, however, show important and constant differences between the two. The hyphæ of *P. sanguineus* usually soon develop red pigments[4] on their walls, and the whole slant looks mainly grenadine red, and scarlet red, scarlet or Brazil red afterwards[5], while the vegetative hyphæ of *P. cinnabarinus* remain perfectly uncoloured; only the porous areas, when eventually formed with development of basidia-initials, take on the characteristic Morocco red, scarlet, scarlet red, and Brazil red colour[5].

On pairing cultures of the two species on malt–agar-coated slides no hyphal fusion between the two could be observed; the hyphæ of the two colonies passed along each other without any fusion and there were abundant coilings (anti-clockwise under the microscope) of some hyphal branches of both, showing distinct inhibition as remarked by Brian *et al.*[6]. If there were thicker coatings of malt agar on slides, there appeared a distinct line of aversion between the two. Malt extract–agar plates were inoculated on the same day by the disk method with cultures of *P. sanguineus* and *P. cinnabarinus* on two sides of the plate at a distance of 3 cm. from each other. In the course of three days *P. sanguineus*, being a faster grower, surrounded the colony of *P. cinnabarinus*, leaving a visible distinct zone of aversion all round (see accompanying illustration). Microscopical examination of both aerial and submerged mycelium at the zone of aversion showed hyphæ of both species crossing each other with no hyphal fusion anywhere and with very pronounced anti-clockwise coiling of some hyphal branches of both.

From these characters it is concluded that the two species are distinct and are not identical, as held by previous workers.

Enhancement of Streptococcal Bacteriophage Lysis by Hyaluronidase

It is well known that most Group A streptococci synthesize hyaluronic acid, which forms the streptococcal capsule, during the early stages of growth, and that mucoid colonies on blood agar are formed by strains that produce considerable amounts of hyaluronic acid. During attempts to propagate bacteriophages active against Group A streptococci, it was found that the organisms which survived and gave secondary growth were invariably mucoid. This observation suggested that the hyaluronic acid capsule might form a barrier between the organism and the bacteriophage and prevent attack. If this were so, then the inclusion of hyaluronidase in the medium might be expected to prevent the formation of a capsule and leave the organism vulnerable to attack by the bacteriophage.

Tests were made to find the smallest amount of purified hyaluronidase (Bengers) which prevented capsule formation in serum broth. In the subsequent tests with phages, five times this concentration was used.

Two phages, which ordinarily gave only partial clearing in broth, were added, together with their respective propagating strains, to plain serum broth containing hyaluronidase. The tubes were incubated for 15 hr. Those tubes containing hyaluronidase showed complete clearing, none of the others showed any evidence of lysis.

Dilutions of phage were then spotted on their respective propagating strains spread over the surface of glucose serum agar plates with and without hyaluronidase; in both cases the titre was higher on the hyaluronidase plates than on the controls (see table).

The effect of the hyaluronic acid capsule on phage action can also be illustrated by using mucoid and non-mucoid variants of one strain. On a 'glossy' non-mucoid variant of type 6, phage *A6* had a titre

TITRATION OF PHAGE ON SOLID MEDIA WITH AND WITHOUT HYALURONIDASE

Strain	Serum glucose agar	Reciprocal of phage dilution				
		10	100	1,000	10,000	100,000
594	Control	CL	+	±	–	–
	„ + hyaluronidase	CL	CL	++	+	±
Type 12	Control	CL	±	–	–	–
	„ + hyaluronidase	CL	CL	CL	++	+

–, No plaques, ±, fewer than 10 plaques, +, 10–50 plaques; ++, 50 per cent lysis; CL, confluent lysis

of 1/1,000 with or without the addition of hyaluronidase. On a 'mat' mucoid variant of the same strain, the titre was only 1/10 without hyaluronidase; but using plates containing hyaluronidase the titre was approximately the same as on the non-mucoid strain.

Streptococci always appear more mucoid in media containing serum, and consequently the effect with hyaluronidase is more striking. Evans[1] has reported the inhibition of phage action by a variety of body fluids. The observations reported here suggest that this inhibition may be due in part to the promotion of capsule formation rather than to phage neutralization. Phage 594 used in this work is that used by Evans[2]. The other phages employed in these tests were given to us by Prof. N. A. Boulgakov, who isolated them from Paris sewage.

An After-effect in Butter-fat irradiated with High-energy Electrons

IN a previous communication[1], a number of the oxidative effects produced in butter-fat by irradiation with high-energy electrons were reported as increasing with decrease of temperature during irradiation. Further examination has now shown that the changes which occur during irradiation are in some circumstances followed by extensive changes after irradiation. and that both are markedly affected by temperature. The main influence of temperature is, in fact, on the after-effect, which shows a surprising maximum reaction-rate in the region of – 20° C.

The effects during and after irradiation are clearly seen in the accompanying table. 1·2-MeV. electrons were used at a superficial dose-rate of 4 × 10[illegible] r.e.p./min. as described previously, and the butter-fat was a fresh sample saturated with air and water at + 37° C. Completely filled polythene dishes with sealed-on polythene-film lids were used to eliminate heating effects associated with the walls of glass vessels and the possibility of gross differences of oxygen content at different temperatures. Each line of the table is the average of duplicate experiments, in each of which a sample was irradiated at a given temperature and distributed in equal portions between a series of glass tubes pre-equilibrated to a range of storage temperatures. All manipulation, which was complete within two minutes of the end of irradiation, was in subdued artificial light and storage was in the dark.

EFFECT OF TEMPERATURE OF IRRADIATION AND STORAGE ON THE PEROXIDE VALUE OF BUTTER-FAT IRRADIATED WITH A DOSE OF 2 MILLION R.E.P. OF 1·2-MEV. ELECTRONS. (THE UNIRRADIATED BUTTER-FAT HAD NO MEASURABLE PEROXIDE VALUE)

Temp. during irradiation (° C.)	Temp. during storage (° C.)	Peroxide (μmol. oxygen/gm.) after storage for		
		0 days	2 days	8 days
–70	–70	3·0	4·2	4·5
	–20		17·0	15·7
	0		5·1	7·3
	+20		4·3	5·1
0	–70	3·0	3·0	5·0
	–20		18·5	17·3
	0		7·1	7·4
	+20		3·1	6·0
+20	–70	1·5	1·6	1·6
	–20		1·5	1·6
	0		1·1	1·0
	+20		1·6	2·3
+37	–70	0·2	0·0	0·6
	–20		0·1	0·7
	0		0·1	0·0
	+20		0·8	1·2

It can be seen that fats irradiated at 0° C. or – 70° C. (on solid carbon dioxide) showed a striking increase in peroxide value[2] during the first two days of storage at – 20° C., compared with increases which were much smaller at 0° C. and barely significant at + 20° C. or – 70° C. Further investigations have shown that the reaction at – 20° C. follows a smooth reaction curve which in some cases does not attain its maximum value until four or five days after irradiation. Irradiation at higher temperatures gave a somewhat different picture. No after-effect was observed after irradiation at + 20° C., while the molten fat at + 37° C. failed to show even peroxide formation during irradiation. The same series of interrelationships was also given with an independent method of following the damage to the fat, namely, the Schibsted method[3], which is normally regarded as measuring aldehydes of high molecular weight. Since the butter-fat is molten above 35° C., semi-plastic at + 20° C. and virtually solid by about – 20° C., it appears possible that the changes are related to the physical state of the fat.

Some indication of the possible mechanism has been given by the demonstration that the typical reaction at – 20° C. occurred in samples which had been held for as long as 24 hr. at – 70° C. after irradiation, but not after three hours at + 20° C. Even 15 min. at + 20° C. (barely time for equilibration to temperature) eliminated three-quarters of the after-effect. These observations indicate the formation, by the radiation, of a reactive intermediary compound which is stable at very low temperatures and rapidly deactivated at room temperature or higher. At temperatures in the region of – 20° C. an intermediate state may exist in which the destructive mechanisms are suppressed, possibly by the decreased mobility, but the temperature is still sufficiently high for some localized reactions to occur.

A partial destruction of the small amounts of antioxidants (mainly tocopherols) present in the fat also occurs during and after irradiation. This can be demonstrated as a reduction of storage-life before typical rancidity develops, and has proved to be parallel to the peroxide value with all samples so far examined. In the present experiments, least destruction occurred with samples melted before, during or immediately after irradiation (storage life two to three days), while samples in which the peroxide had risen to high values at – 20° C. had no residual storage life. It is not certain, however, that the antioxidant disappears at the same stage of the reaction at all temperatures, and further investigation is required before the part it plays in the whole series of changes can be suggested.

The relationship between these effects and those of normal autoxidation, or the after-effect observed spectroscopically by Mead[4] with X-irradiated linoleic acid, is still obscure. Qualitatively similar effects have also been shown with 40-kV. X-rays.

This work has been carried out with the co-operation of the Medical Research Council as part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research. We are grateful to Mr. J. W. Boag and Mr. D. Moore, of the Radiotherapeutic Research Unit of the Medical Research Council, Hammersmith Hospital, for carrying out the necessary irradiations.

Differences in the Biological Activity of 2 : 3 : 5 : 6-Tetrachloronitrobenzene and its Isomers

IN a recent paper[1], differences in the metabolism of 2 : 3 : 5 : 6-tetrachloronitrobenzene and the 2 : 3 : 4 : 5 compound in the rabbit have been described. Preliminary investigations in these laboratories have shown other differences between these compounds.

The 2 : 3 : 5 : 6 symmetrical isomer, formulated as a dust, has been used successfully to control *Botrytis* disease of lettuce[2] and dry rot of seed potatoes[3], and it has been shown to inhibit the sprouting of potatoes[4,5].

In our experiments, against normal strains of *Fusarium caeruleum* (Lib.) Sacc. in culture, 2 : 3 : 4 : 5 tetrachloronitrobenzene has inhibited radial growth more than the 2 : 3 : 5 : 6 isomer. Two of the mutant strains produced by McKee, and shown by him to be resistant to the 2 : 3 : 5 : 6 isomer[6], have been tested, and found to be less resistant to the 2 : 3 : 4 : 5 isomer. Both retained resistance to 2 : 3 : 5 : 6-tetrachloronitrobenzene after five months growth in its absence. In the accompanying table are results from an experiment in which subcultures were grown under the influence of the vapour from 0·01 gm. of the pure isomers deposited centrally in the lids of the Petri dishes.

MEAN INCREASE OF COLONY DIAMETER (MM. PER DAY). MCKEE STRAIN *B*

Strain	Tetrachloronitrobenzene isomers None	2 : 3 : 5 : 6	2 : 3 : 4 : 5
Normal	7·0	4·5	3·7
Mutant, resistant	5·8	5·1	3·7

When 1-lb. batches of Craig's Defiance potatoes were each dressed with 2 gm. of a 2 per cent dust of each isomer, and stored in closed tins until untreated controls were sprouting profusely, the following mean sprout weights were obtained :

Tetrachloronitrobenzene isomers None	2 : 3 : 5 : 6	2 : 3 : 4 : 5
26·8 gm.	10·4 gm.	27·9 gm.

With treated potatoes in small clamps, some inhibition of sprouting occurred with seed treated with the 2 : 3 : 4 : 5 isomer, but less than that in clamps treated with the 2 : 3 : 5 : 6 isomer. It is concluded that 2 : 3 : 4 : 5-tetrachloronitrobenzene is a less powerful inhibitor of potato sprouting than is the 2 : 3 : 5 : 6 isomer.

Application of the isomers as 5 per cent dusts to lettuce in boxes resulted in a visible check to growth, which was quickly overcome in the case of the 2 : 3 : 5 : 6 isomer but which persisted in plants treated with the 2 : 3 : 4 : 5 isomer and produced a significant reduction in dry weight of the final crop ($P = 0.001$). It is concluded that both isomers can inhibit the growth of lettuce, but the 2 : 3 : 4 : 5 isomer is a more powerful inhibitor. Preliminary field-tests have shown the 2 : 3 : 4 : 5 isomer to be less effective than the 2 : 3 : 5 : 6 in controlling *Botrytis* disease of lettuce.

The limited examination yet made of 2 : 3 : 4 : 6-tetrachloronitrobenzene suggests it is more active than the other two isomers in inhibiting the growth of both *Fusarium caeruleum* and *Botrytis cinerea* in culture, and the sprouting of potatoes, but may be less inhibitory towards the growth of lettuce.

The investigations are continuing.

Mode of Action of Agents giving Protection from Radiation

A CONSIDERABLE number of compounds is now known to be capable of protecting animals against X-rays and other radiations. Among the most effective of these are sodium cyanide and sodium azide[1], and thiourea[2]; alcohols[3] and amines[4] are active at higher concentrations. X-rays degrade polymethacrylic acid in aerated aqueous solutions, and the extent of the reaction could readily be followed by changes in viscosity with a high molecular weight sample of the polymer[5]. Table 1 shows that the degradation is reduced in the presence of substances which are protective agents in biological experiments. Since the compounds were placed in the same order of effectiveness in both tests, it is suggested that similar chemical reactions are involved. Allyl thiourea, which does not appear to have been examined biologically, was found in our work to be a highly effective protective agent.

Since polymethacrylic acid is not degraded by comparable doses of X-rays in the absence of air (see

Table 1. FALL IN VISCOSITY OF POLYMETHACRYLIC ACID (0·025 PER CENT NEUTRALIZED TO pH 7) ON IRRADIATION WITH 1,000 r. (200-KV X-RAYS) IN THE PRESENCE OF COMPOUNDS GIVING PROTECTION AGAINST RADIATION

Protective agent	% fall in viscosity*
None	52
Solution saturated with nitrogen	2·0
4×10^{-4} *M* potassium cyanide	7·9
1×10^{-4} *M* allyl thiourea	0·0
8×10^{-4} *M* thiourea	14·0
8×10^{-4} *M* sodium azide	16·9
8×10^{-4} *M* methylamine	49
8×10^{-4} *M* methanol	40
250×10^{-4} *M* n ethanol	20

* Determined at a shear rate of 50 sec.$^{-1}$

Table 1) the primary products of the radiolysis of water, that is, hydrogen atoms and hydroxyl radicals, cannot be responsible for the breaking of carbon–carbon bonds in this system. The perhydroxyl radical, HO_2, is known to be formed by X-rays in the presence of oxygen and seems to be the most probable agent responsible for the degradation observed. Hydrogen peroxide, another product of irradiation, does not by itself react with the polymer even in high concentrations. These results indicate that the compounds examined here giving protection against radiation may react with perhydroxyl radicals possibly by adding an oxygen atom, for example, cyanide to cyanate, amine to amine oxide, sulphur compounds to sulphones or sulphoxides. The possibility that these compounds also react with hydroxyl radicals was tested in the following experiment.

Table 2. POLYMERIZATION OF AN AQUEOUS SOLUTION OF METHACRYLIC ACID (20 PER CENT) BY IRRADIATING WITH 10,000 r. (200-KV X-RAYS)

Solution	% Monomer polymerized
Saturated with nitrogen	51·5
Saturated with nitrogen + 0·1 *M* thiourea	72·5
Saturated with nitrogen + 0·1 *M* allyl thiourea	51·0
Saturated with nitrogen + 0·1 *M* ferrous sulphate	20·0
Aerated	2·4
Aerated + 0·8 *M* thiourea	22·5

Hydroxyl radicals are catalysts in the polymerization of vinyl compounds, and in deoxygenated solutions methacrylic acid is readily polymerized by X-rays. Table 2 shows that this reaction is not inhibited by thiourea or allyl thiourea at a concentration sixty and one thousand times respectively of that needed to protect polymethacrylic acid against X-ray degradation; in fact, the polymerization in the presence of oxygen is promoted by thiourea. On the other hand, ferrous sulphate, which is well known to react with hydroxyl radicals, prevents the polymerization. Some at least of the compounds giving protection against radiation therefore do not react with hydroxyl radicals, whereas they all react with the radical responsible for the degradation. These experiments lead us to suggest that these substances protect against radiations *in vivo* by competitively removing perhydroxyl radicals formed in the presence of oxygen, and that it is the reaction of these radicals with vital cell constituents which brings about those of the biological effects (for example, radiation sickness) which can be counteracted by these chemicals. The protection afforded to animals by reduced oxygen tension[6] is in agreement with this hypothesis.

We wish to thank Prof. A. Haddow for his interest and encouragement, and Mr. C. A. Greatorex (Physics Department, Royal Cancer Hospital) for carrying out the X-ray irradiation. This investigation has been assisted by a special grant from the Anna Fuller Fund and by grants to the Royal Cancer Hospital and Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

The Stauromedusan *Craterolophus tethys* Clark in British Waters

THE stauromedusan genus *Craterolophus*, although bipolar, has appeared nevertheless to have a curiously restricted distribution[1]. The type species, *C. tethys* Clark 1863 [2], seems never to have been recognized outside the type locality Heligoland, though frequently reported in that region. The southern form, *C. macrocystis* von Lendenfeld[3], the specific status of which is in some doubt[1], occurs only on the New Zealand coast. Recent observations indicate that the northern form at least is more widespread than has been supposed.

Stauromedusæ make sporadic and infrequent appearances on the Yorkshire coast. *Haliclystus octoradiatus* and a supposed *Lucernaria campanulata* were first recorded from the Scarborough area in 1913 [4], but neither was seen again for nearly ten years[5,6]. Since the second appearance there have been no further records or reports of their occurrence; but in 1950 a chance find by Dr. W. S. Bullough at Robin Hood's Bay, Yorkshire, led to the discovery, after protracted search, of several specimens of what was thought to be a species of *Lucernaria*. This now proves after detailed examination to be, in fact, *C. tethys* Clark. The same species was again present, now in some numbers, in the summer of 1951, though in the intervening spring its absence was made the more conspicuous by the sudden appearance of *Haliclystus octoradiatus* (Lamarck).

It is quite certain that these appearances of *C. tethys* are not invasions by a species new to Britain, for by a fortunate chance a solitary specimen from one of the Scarborough collections mentioned above[4,5] is in the possession of this Department. Though allegedly *L. campanulata*, it is identical with the recent material. There is evidence, too, that the species has appeared in other localities. Johnston[7] described a *Lucernaria convolvulus* from Berwick Bay which is almost certainly not *L. campanulata* Lmx. to which he afterwards equated it[8], but on the other hand agrees more closely with *C. tethys*[1]. Johnston further considered that his specimens belonged to the same species as others found on the Devon coast. This is of some interest, as a recent photograph of a specimen from this same region[9] seems more likely to be of *C. tethys* than of *L. campanulata*, to which it, too, is ascribed.

It seems very probable that *C. tethys* has appeared at intervals over a considerable stretch of the east and south coasts of Britain. It remains to be discovered, whether it is established there, or whether it is a case of sterile distribution with periodical recruitment occurring from an outside source as a result of favourable circumstances at the time of reproduction. The latter alternative seems the less likely, since so far as is known the planula stage in the development of Stauromedusæ is of short duration, and therefore unlikely to be transported over any great distance.

I wish to thank Mr. P. G. Corbin both for the loan of specimens of *Lucernaria* and for much helpful discussion and assistance with the literature.

Uricotelism in the Common Indian Apple-Snail, *Pila globosa* (Swainson)

NITROGEN catabolism in animals has been assessed partly by analysis of the excretory products and partly by the identification of the enzymes in the liver or hepatopancreas. Since Strohl reviewed the excretory mechanism in the Mollusca, work on a few European marine, freshwater and terrestrial gastropods has been extended[1-4]. Since no data are available for an amphibious snail and no parallel record for an Indian form, so far as we know, a study was undertaken on the common Indian apple-snail *Pila globosa* (Swainson). This particular form, besides being amphibious, develops through a cleidoic egg. The most active period of this snail's life is during the rainy season, when it lives in fresh water and feeds and also breeds on the banks. With the approach of the winter it becomes less active and burrows in the mud to æstivate for the rest of the year until the onset of the next rainy season.

During the course of the investigations, it was noticed that the uric acid content of the nephridium, which in this snail consists of an anterior and a posterior renal chamber, was rather low in the snails collected from their natural environment during the rainy season—being only 7·68 mgm. per gm. dry weight of the tissue in the anterior chamber and almost nil in the posterior renal chamber. After these snails have been maintained in the laboratory in wet jars in the shade for about a month, the quantity of uric acid increased to about 60 mgm. per gm. dry weight of the tissue in the anterior, and 14 mgm. in the posterior, renal chamber. When some of these snails were allowed to æstivate in the mud in the laboratory for a couple of months or more, the uric acid content of the nephridium gradually increased still further, as was shown by periodic estimations of the uric acid in their nephridia. It attained a maximum of about 102 mgm. per gm. dry weight of the tissue in the anterior, and 42 mgm. in the posterior, renal chamber, in the snails which had æstivated for more than six months.

A few of these æstivating animals with high uric acid content of the nephridium were selected and kept in water in small glass bowls, in which they were left for a number of days and periodically exposed to bright sunlight. They were examined one by one after regular intervals and the uric acid content of their nephridia determined. It was found that the quantity of the uric acid decreased with the length of time the snails were kept in the water (see accompanying table).

Period in water	Uric acid* Anterior chamber	Uric acid* Posterior chamber	Total
Nil	102·38	42·58	144·95
15 days	78·3	50·88	109·18
21 days	79·04	10·23	80·27
27 days	29·88	Nil	29·88

* Uric acid content in mgm. per gm. dry weight of the tissue. Two or three snails were selected for each estimation.

Attempts were also made to see if this uricogenesis in *Pila globosa* could be correlated with certain enzymes present in the hepatopancreas and the nephridium of the snail. Following the technique of Baldwin[1] and Sumner and Somers[5] for arginase and xanthine oxidase respectively, it was possible to demonstrate the occurrence of both these enzymes in the hepatopancreas of *Pila globosa* in appreciable quantities. However, neither of these enzymes could be detected in the nephridium of *Pila globosa*. Whether these enzymes could be directly related to the æstivation of *Pila* is difficult to say[6,1], and so far it has not been possible to find any appreciable difference in the arginase content of the æstivating *Pila* and those living in an aquarium. The work is, however, being extended by one of us (B. B. S.).

All our experiments were carried out at room temperature with controls and blanks simultaneously.

Ultra-Violet Papyrography: an Automatic Analytical Apparatus using Filter Paper without a Colour Reagent

A NEW analytical technique using filter paper and termed 'ultra-violet papyrography'[1] has been developed in these laboratories (Fig. 1).

The apparatus uses light from the ultra-violet (2537 A.) to visible region for the four methods.

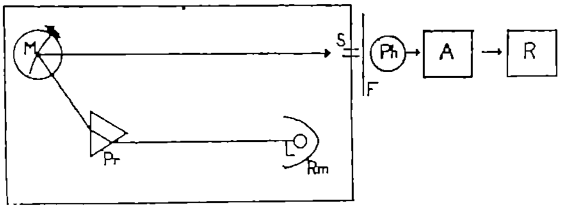

Fig. 1. *Rm*, Parabolic reflector for ultra-violet radiation; *L*, high-power mercury lamp; *Pr*, quartz prism for ultra-violet, *M*, concave reflector for ultra-violet; *S*, adjustable slit; *F*, filter paper; *Ph*, photomultiplier for ultra-violet; *A*, amplifier, *R*, recorder

(1) densitometry of finished filter papers prepared by paper chromatography or electromigration; (2) automatic paper chromatography; (3) automatic paper electromigration; (4) automatic paper electrochromatography.

Substances absorbing in the ultra-violet region may readily have their R_F values determined by use of ultra-violet light in method 1. In this case the finished filter paper is moved from the starting line to the solvent front. With methods 2, 3 and 4, a beam from a monochromator is projected on the fixed paper, and a sample is run by use of a developing solvent or an electric current. By these latter methods a quick automatic analysis of colourless substances is realized.

The apparatus can be used for both qualitative and quantitative analyses. By the methods of paper chromatography described, there have been obtained ultra-violet papyrograms for flavonoids[2], alcohol xanthates[3], and some organic bases[4]. Thus the accompanying papyrogram (Fig. 2) was obtained by ultra-violet densitometry (2537 A.) applied to the finished paper chromatogram of the hydrolysate of deoxyribonucleic acid.

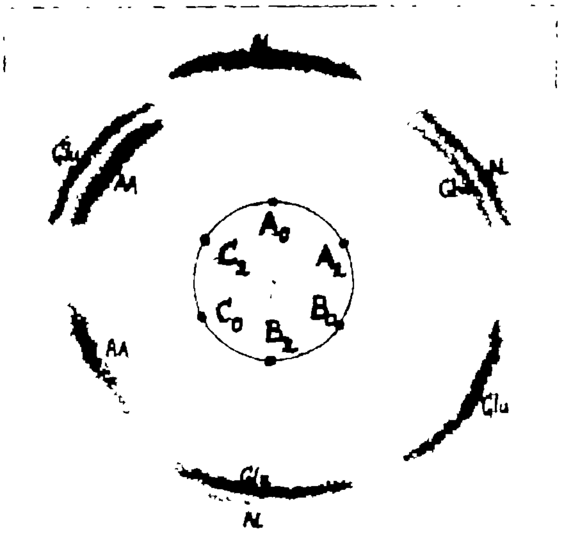
A Simple Paper Chromatographic Method for the Study of Transamination Reactions

Recently, the application of paper chromatography to the study of transamination reactions has been reported by several workers. The method adopted by Fincham[1] is based on the visual comparison of the spots and as such it is only roughly quantitative. Tulpule and Patwardhan[2] reported a method based on conversion of α-ketoglutaric acid and pyruvic acid to the respective dinitrophenylhydrazones and estimating them colorimetrically after paper chromatographic separation. This method, even though claimed to be accurate, is obviously time-consuming and tedious. While our work on transaminating systems in Indian pulses was in progress, Awapara's paper[3] appeared in which the distribution of transaminases in rat organs was followed by using unidimensional paper chromatography.

In this communication is presented a simple method for the detection and quantitative determination of transaminase activity in plant tissues using the circular paper chromatographic technique[4–6], which is now being continuously used in this laboratory.

The following reactions have been studied by us (*a*) alanine + α-ketoglutarate → glutamic acid + pyruvate; (*b*) glutamic acid + pyruvate → alanine + α-ketoglutarate; (*c*) aspartic acid + α-ketoglutarate → glutamic acid + oxalacetate.

The enzyme was prepared by extracting the powder of resting seeds (*Phaseolus radiatus*) with water (1 : 4, w/v) and dialysing the centrifuged extract against distilled water for 24–48 hr. at 0–5° C. The dialysed extract was centrifuged and the cloudy supernatant used in these experiments. The reaction mixture containing 0·1 c.c. of $M/15$ amino-acid, 0·1 c.c. of $M/15$ α-ketoglutaric or pyruvic acid (neutralized with sodium hydroxide), 1 c.c. of $M/15$ phosphate buffer (*p*H 7·4) and 0·8 c.c. of enzyme solution, was incubated at 35° C. for 2 hr. and the



Circular paper chromatogram showing presence of transaminating systems in green gram (*Phaseolus radiatus*) The reaction mixtures were spotted at positions marked on the circumference of the circle. A_0, B_0, C_0, refer to the reaction mixtures at 0 hr for the systems mentioned in the text; A_2, B_2, C_2, to the same after 2 hr. incubation reaction stopped by the addition of an equal volume of absolute ethanol. The protein precipitated was centrifuged off and 20 µl. of the clear supernatant were spotted on the paper and developed as described in earlier publications[5,6].

The accompanying photograph is of a typical chromatogram showing the presence of the above systems in green gram (*Phaseolus radiatus*).

The progress of the reaction was followed quantitatively by estimating the amino-acids by the following method[7]. The colour on the chromatogram was developed by spraying with 0·5 per cent ninhydrin in 95 per cent acetone, heating at 65° C. for 30 min., cutting off the individual amino-acid bands, extracting the colour with 4 c.c. of 75 per cent ethanol containing 0·2 mgm. of $CuSO_4,5H_2O$, and measuring the colour intensity with a Klett–Summerson photoelectric colorimeter using a green filter (540 mµ). An interesting feature is the effect of added cupric ions, which increases the tone and colour intensity considerably. The method is highly sensitive, simple and can be easily carried out in a short time.

Full details of this investigation will be published in the *Journal of the Indian Institute of Science*.

Self-branching of Vinyl Polymers

The physical properties of a substance consisting of long-chain molecules are modified considerably if branches are introduced into the molecules, and a method for estimating the number and length of the branches in a synthetic addition polymer would be of very great value. That some types of vinyl polymers are, in fact, branched has been demonstrated in this laboratory by an examination of the molecular weight (M) and length (d) of polyvinyl acetate in suitable solvents[1]. According to light-scattering theory, the value of M/d^2 should be independent of M. In fact, M/d^2 increases in value as the temperature of synthesis is increased, showing that the polymer becomes more compact in structure, that is, branching becomes more pronounced.

During the polymerization of a vinyl monomer, branching occurs owing to a growing radical attacking a dead polymer molecule, abstracting a hydrogen atom and forming a free valency in the polymer chain; growth of a side-chain can begin at this point. It has been demonstrated that if a monomer is polymerized in the presence of the polymer of a second monomer, it is possible to isolate material containing both types of monomer unit[2]; during the polymerization, side-chains must have been grafted on the dead polymer. A new method has now been developed for studying the branching reaction using a single monomer, and preliminary results obtained using styrene and vinyl acetate are presented here.

Monomeric styrene labelled with carbon-14 was polymerized in the presence of inactive polystyrene of average molecular weight about 500,000, the conditions being adjusted so that the active monomer yielded polymer of fairly low molecular weight (about 50,000). A small fraction of the material of highest molecular weight was isolated and it was found to possess an appreciable amount of activity. In order to calculate the amount of activity which was chemically combined with the high polymer, it was necessary to perform a blank experiment and to make allowance for incomplete separation of active low polymer and inactive high polymer.

Comparison of the activity grafted on the high polymer with the activity of polymer formed directly from the active monomer would have permitted calculation of the number of branches in the system if the average length of the branches had been known. It was assumed that the average length of the branches was equal to half the average chain-length of the linear polymer formed at the same time. The rate of formation of branch-points, which is equal to the rate of transfer to polymer, is $k_x n(M.U.)$, where n is the number of growing centres in the system and $(M.U.)$ is the concentration of monomer units incorporated in the polymer. The value of n can be calculated from the observed rate of polymerization, the concentration of monomer and the velocity constant for chain-growth. Provisional values in litre mole^{-1} sec.$^{-1}$ for the constant k_x are 0·35 at 130° C. and 0·56 at 154° C., giving approximately 7 kcal. as the energy of activation. At 154° there is one branch of 115 monomer units for about 7,920 monomer units in the linear polymer. If the polymerization of styrene is carried to high conversion at elevated temperatures, an appreciable number of branches may be formed; but at temperatures below about 100° C. in reactions allowed to proceed only to small conversions, branching must be negligible.

The experimental procedure was altered slightly for studying the branching of vinyl acetate. Unlabelled monomeric vinyl acetate was polymerized in the presence of labelled polyvinyl acetate of high molecular weight (about 660,000), the conditions being such that a polymer of average molecular weight about 100,000 was produced. A value of 8·1 litres mole^{-1} sec.$^{-1}$ was obtained for the velocity constant k_x at 40° C. At this temperature there was one side-chain of 582 monomer units on the average for 2,760 monomer units combined in the form of linear polymer. Clearly, transfer to polymer and branching are of more significance in the polymerization of vinyl acetate than in that of styrene, owing to the much higher reactivity of the vinyl acetate radical.

The results indicate that the value of the velocity constant k_x is similar to those for the velocity constants for transfer to monomer (k_f) and for transfer to small molecules (k_f'), which can be taken as models for the monomer unit in the polymer[3]. For styrene at 130°, k_x was found to be 0·35 litre mole^{-1} sec.$^{-1}$, while k_f and k_f' for ethyl benzene are calculated as 0·34 and 0·45 litre mole^{-1} sec.$^{-1}$ respectively. In the case of vinyl acetate, k_x at 40° is 8·1 litres mole^{-1} sec.$^{-1}$, while a value of about 5 litres mole^{-1} sec.$^{-1}$ has been quoted for k_f at 50° C.

It can be predicted that branching is most likely to be important for monomers which yield reactive radicals, for example, vinyl chloride; branching might be particularly pronounced with this monomer, as the abstraction of a chlorine atom by a free radical should occur more easily than the abstraction of a hydrogen atom.

The results of experiments with further monomers, and full details of the experimental procedure, will be published elsewhere.

Anomalous Specific Heat of Chromium Oxide (Cr_2O_3) at the Antiferromagnetic Curie Temperature

RECENTLY, some observations have been published of phenomena related to the second-order transition of chromium oxide (Cr_2O_3) at the antiferromagnetic Curie temperature; for example, the change of lattice constants[1] and the anomalous absorption of high-frequency electromagnetic energy[2]. However, so far as I am aware, no measurements of an anomalous specific heat have been published. In the present communication, measurements are presented of C_p between 100° and 350° K. and of the magnetic susceptibility χ between 77° and 550° K., which were made on samples of the same preparation of chromium oxide.

The compound was prepared by firing ammonium dichromate in air at 1,000° C. The susceptibility was measured on a sample of 280 mgm. of the resulting oxide by the Faraday' method (force on the specimen in an inhomogeneous magnetic field). The torsion spring balance used was an improved design of that described elsewhere[3]. The results are plotted in Fig. 1. It is remarkable that the values of χ at low temperatures are lower than those found by Foex and Graff[4], whereas the high-temperature values of χ seem to be somewhat higher than was found by these investigators. The dip of the curve which is believed to indicate the antiferromagnetic Curie temperature is found at 45° C.

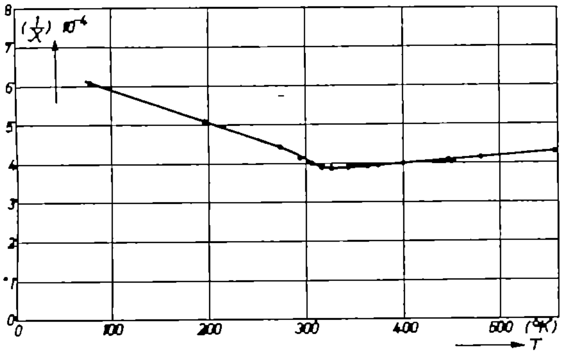

Fig 1 Reciprocal susceptibility per gram of chromium oxide as a function of temperature

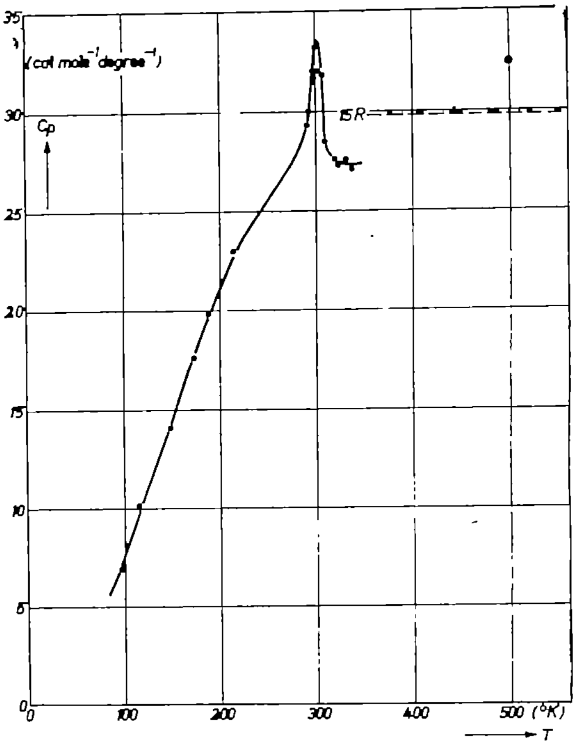

Fig. 2. Molecular specific heat of chromium oxide as a function of temperature

The specific heat was investigated on a sample of 29·6 gm. The substance was well enough sintered to form one solid piece, so that no container had to be used for the calorific measurements. The apparatus and method were the same as described by Volger[3]. The results are given in Fig. 2. Obviously, the anomaly of C_p at about 35° C. is due to the final disappearance of the antiferromagnetic ordering. The very steep drop of C_p was confirmed by the continuous heating method (analysis of the drift of temperature caused by a very small supply of heat[5]). Similar anomalies of the specific heat have been observed with oxides of other transition elements exhibiting antiferromagnetism; for example, manganese oxide (MnO) and dioxide (MnO_2), and iron oxide (FeO) and also with copper oxide (CuO)[6,7].

In a recent paper, Foex[8] states that his unpublished measurements of the thermal expansion or the specific heat of chromium oxide indicate a Curie point of this oxide at 40° C.

I am much indebted to Mr. F. C. Romeyn for preparing the compound, and to Mr. J. H. Aalberts for help during the measurements.

Thermodynamics of Irreversible Electrochemical Processes

In a recent paper, DeGroot and Tolhoek[1] have attempted, by means of an application of the thermodynamics of irreversible processes, to extend Guggenheim's[2] ideas concerning the activities of ions and the electrical potential difference between two phases. To this end they have considered a medium showing a bulk motion and in which chemical reactions and flows of energy, matter and electricity are occurring; two different mathematical treatments of this system are given.

As a result of their second treatment, these authors deduce that electrical potential differences are (in principle) measurable apart from differences in ionic chemical potentials, provided that an electrical space charge is present, that is, in nearly insulating media but not in media showing any appreciable degree of electrical conductivity. This conclusion is obtained from the fact that the thermodynamic equations of this method of treatment, provided that there is no space charge, contain the chemical potential μ_i of the ith ionic species and the electrical term $e_i\varphi$ (where φ is the electrical potential of the medium and e_i the ionic charge) only in the combination $\bar{\mu}_i = \mu_i + e_i\varphi$, that is, as the electrochemical potential of i; if a space charge exists, however, the equations contain additional terms involving φ but not μ_i.

Now both the second and first methods of treatment involve the use of the following thermostatic equation for the change in intrinsic energy of a system:

$$\mathrm{dU} = Td S - p d V + \sum_i \mu_i d n_i, \qquad (1)$$

where the symbols have their usual thermodynamic meaning. Since the change in U is quite independent of the path followed, it is quite correct to apply this equation to any process whatever occurring in the system, reversible or irreversible. However, it is subject to the restriction that the system does no specialized work, that is, no work which cannot be included in the second and third terms on the right of (1). It is therefore quite erroneous to apply it to a system containing electrical charges and potentials, which can perform electrical work.

It is readily ascertained from thermostatic first principles that, when a system can perform specialized work, a term representing the maximum specialized work that it is capable of performing under reversible conditions must be added to (1). The equation is then still applicable to an irreversible change, for the same reason as before; but it must be noted that the specialized work term is then not equal to the specialized work which has actually been performed in the process. In the case of electrical work, the correct form of the equation is obtained by replacing the chemical potentials μ_i in (1) by the electrochemical potentials $\bar{\mu}_i$ as defined above:

$$\mathrm{dU} = Td S - p d V + \sum_i \bar{\mu}_i d n_i. \qquad (2)$$

It is this expression, not (1), which must be taken as the basis of the thermodynamic treatment of an irreversible electrochemical process, although the erroneous use of (1) has apparently been in vogue for a number of years[3].

If now the first method of DeGroot and Tolhoek is carried through using (2) in place of (1) as the only modification, it will be found that the equations finally obtained do indeed contain μ_i and φ only in the combination $\bar{\mu}_i$; in particular, the thermodynamic force acting on the ith ion is given by:

$$X_i = F_i - T \operatorname{grad}(\bar{\mu}_i/T), \qquad (3)$$

where F_i is the non-electrical external force acting on the ion (the effect of external electrical forces is already included in the φ term of $\bar{\mu}_i$). Equation (3) leads to the usual and well-known results when applied in any particular problem. Thus from this first treatment alone it is seen that no thermodynamic measurement can ever determine separately either the electrical or non-electrical part of $\bar{\mu}_i$, no matter whether or not a space charge exists in the system.

The second method of DeGroot and Tolhoek can also be carried through with the same modification, but then some rather peculiar equations result. In this method, instead of the intrinsic energy U, used in the first case, a quantity $\overline{\mathrm{U}}$ is employed; this is said to be the "intrinsic energy, including electrical energy", and is defined as:

$$\overline{\mathrm{U}} = \mathrm{U} + e\varphi, \qquad (4)$$

where e is the total electric charge in the system. However, the intrinsic energy U does, by definition, include the totality of the energy contained in the system, so the addition of the term $e\varphi$ is tantamount to including the electrical energy twice over. Thus $\overline{\mathrm{U}}$ as defined by (4) is a new thermodynamic function which might conceivably have some particular applications, but which certainly cannot be used in place of U in equations (1) and (2).

The whole of this second method of treatment must therefore be considered invalid. This leaves us with the conclusion, drawn from the revised first treatment, that thermodynamic measurements on any system will never give us anything other than the electrochemical potentials $\bar{\mu}_i$ of the ionic species concerned. This is in complete agreement with Guggenheim's original conclusions. The question of whether or not the electrical and non-electrical parts into which the $\bar{\mu}_i$ may be formally split have any real physical significance is, however, quite another matter and cannot be discussed here.

Thermal Decomposition of Normal Paraffins

During the past two years, four papers dealing with the thermal decomposition of normal paraffin hydrocarbons by Sir Cyril Hinshelwood and his collaborators have been published in the *Proceedings of the Royal Society*. The work described in them is based upon the following assumptions: (1) that primary decomposition, in the simplest case, involves the formation of methane, and the corresponding olefine; (2) that reaction is inhibited by the addition of nitric oxide to the paraffin, and may therefore be assumed to be initiated by free radicals, and carried forward by a chain mechanism; (3) that the rate of the process mentioned under (1) can be measured by observing the rate of change of pressure at constant volume and temperature.

Before the War, one of us with various collaborators had shown that, in the case of ethane: (1) primary hermal decomposition of the hydrocarbon results n hydrogen and ethylene only; this process is nhibited by the addition of nitric oxide to the ethane; (2) the formation of methane, and under certain conditions of methane and polymer together, s secondary to the formation of hydrogen and ethylene. The formation of methane, or of methane and polymer together, which is a measure of the rate of disappearance of C_2-hydrocarbon, is the result of a single time-determining process, the rate of which s not diminished but slightly accelerated by the presence of nitric oxide.

The behaviour of ethane might be supposed to be unique, and we assume that for this reason this work has not been referred to in the papers we have mentioned. We have now proved, however, that the thermal decomposition of propane follows exactly the same course. This fact, and others of which we give details in a paper which has been communicated to the Royal Society, appear to us to justify the claim that the manner in which normal paraffin hydrocarbons decompose when heated is that which we have described. The locus of the rupture of the carbon chain is that of the ethylene bond in the product of the primary olefine. In the case of ethane and propane there can, of course, be only one olefine. In the case of butane one would expect that the primary olefine would be 1-butylene, from which the secondary products would be methane, possibly with some polymer, and propylene. But in the region of our experiments a shift in the position of the double bond would give rise, in the first instance to some dimethyl-ethylene, the secondary products from which would be ethane and ethylene. This is what is actually observed.

We believe that the results which we have obtained places our knowledge of this very important set of reactions on a firm experimental foundation.

Clifford G. Silcocks

Gloucester Technical College.

Morris W. Travers

University, Bristol.
Sept. 29.

It is not correct to say that the work from this laboratory referred to is based upon the 'assumptions' (1), (2) and (3) of the communication from Mr. C. G. Silcocks and Prof. M. W. Travers. That the reactions are partly chain reactions, and that in many cases pressure change is quantitatively proportional to decrease in amount of original paraffin, represent considered conclusions from detailed experiment. 1) has never been stated: the formation of methane and olefine has been given as one of several simultaneous modes of decomposition of the higher paraffins.

The writers appear to think that the primary and predominant formation of ethylene and hydrogen from ethane is incompatible with a chain reaction nvolving alkyl radicals. Reference to almost any text-book on chemical kinetics shows that this would be an error. (According to a generally accepted scheme—not devised by us—the ethylene is formed by breakdown of ethyl radicals.)

The implication of (3), that work in this laboratory has uncritically used change of pressure as a measure of reaction-rate, is wholly unfounded. Detailed analyses at different stages of various reactions of paraffins have been made repeatedly, and indirect tests that the kinetic conclusions are independent of possible errors from this source have also been applied. One of the latest published sets of analyses is in *Proc. Roy. Soc.*, A, 214, 20 (1952), and here it is again specifically shown that change of pressure gives a good measure of initial rate. The results also contradict decisively Prof. Travers's contention that the higher paraffins would give primarily olefine and hydrogen only. With normal butane at 530° C. and 1,400 mm. initial pressure, when the increase of pressure is 145 mm. the percentages of hydrogen, butene, methane and ethane in the products are, respectively, 2·14, 4·1, 31·4 and 13·4; when the increase of pressure is 357 mm. these percentages are, respectively, 2·14, 3·9, 32·9 and 14·5 (the analyses are by mass spectrometer). The other constituents are also consistent with primary formation of lower paraffin and olefine.

Ethane itself could not, of course, give methane and olefine in one step; that it gives methane by some process is already known. Propane does the same; but this cannot have much bearing on the primary behaviour of higher hydrocarbons, nor upon the question whether and to what extent the reactions involve chain processes. Steacie and Puddington[1] have shown that the primary decomposition of propane gives approximately equal amounts on one hand of propylene and hydrogen and on the other of methane and ethylene.

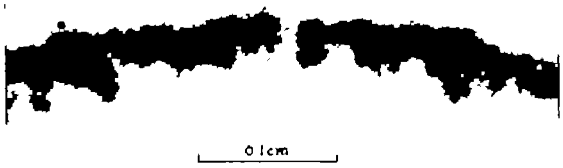
Autoradiography of Metal Surfaces using a Radiochemical Method

A number of methods have been suggested for the autoradiographic study of metal surfaces. Variations of surface composition have been detected using differences in nuclear reactions occurring during irradiation[1], differences in radioactivity produced as a result of irradiation[2,3], and differences in contact potential leading to differences in adsorption of charged radioactive material[4]. The method described in this communication uses the different chemical reactivities of the various metal components towards some radioactive substance that forms a localized radioactive reaction product on the metal surface.

Experiments were carried out with amyl iodide containing some of the iodine-131 isotope, which has a half-life of eight days and emits both β- and γ-rays. The liquid as obtained had a specific activity of 1·5 mC./gm. It had an amber colour and probably contained free iodine, and it seems likely that this iodine, rather than the amyl iodide itself, was responsible for the chemical reactions observed.

When the liquid was placed on a clean copper surface, allowed to remain for fifteen seconds and wiped off with filter paper, a considerable amount of radioactivity remained on the copper surface. Autoradiographs of the copper surface were taken and measurements showed that the equivalent of 150 atomic layers of iodine was present on the copper surface, almost certainly in a chemically combined form. On a mild steel surface under the same conditions, the amount of activity was much less, equivalent to ten atomic layers only. Washing with cold



Autoradiograph of steel surface showing location of copper fragments transferred during sliding

water did not affect the activity on the copper; but it removed all but $2\frac{1}{2}$ iodine layers from the steel surface. It is possible that this residual iodine layer was of monolayer thickness only, the factor of $2\frac{1}{2}$ being the ratio of real to apparent surface area for the lapped steel specimen[5].

The accompanying illustration shows an autoradiograph of the friction track produced by a clean, hemispherically ended copper specimen sliding on steel under a load of 1 kgm., after which the iodine solution was applied for fifteen seconds, the surface washed with cold water and a two-day exposure given on 'No-Screen X-Ray' film. The copper wear fragments transferred to the steel are shown as black circular patches along the (curved) sliding track, while the background due to the steel is nearly invisible. The general appearance of the friction track is very similar to one shown by Rabinowicz and Tabor[6], who obtained their autoradiograph by an entirely different method using a radioactive copper specimen.

Of a number of metals and alloys examined, silver, chromium, lead and copper react most strongly with the iodine (~ 200 atomic layers); indium, tungsten carbide and brass react less vigorously (~ 50 layers); aluminium, bismuth, nickel, antimony, tin, cadmium and mild steel produce still thinner films (~ 15 layers); while zinc and titanium take up only three atomic layers.

The radiochemical method would appear to have considerable potentialities in surface autoradiography. Since only the surface itself is activated, good resolution can be achieved, while flexibility is ensured by the large number of radioactive chemicals and solvents that can be used to achieve a difference in the radioactive intensity at various regions on the surface.

Gravitational Instability of a Turbulent Medium

CHANDRASEKHAR has derived in a very elegant manner[1], from his theory of density fluctuations in an isotropic homogeneous turbulence field[2], the generalization to a turbulent medium of Jeans's criterion for the stability against inhomogeneity of an infinite quiescent homogeneous medium. The expression which he obtains may be written:

$$\lambda^2 = \frac{\pi}{G\rho}\left(c^2 + \tfrac{1}{3}\overline{u^2}\right)$$

$$= \frac{\pi}{G\rho}\left(\gamma\frac{k\theta}{m} + \tfrac{1}{3}\overline{u^2}\right), \tag{1}$$

where λ is the critical length for stability, c is the speed of sound in the medium, θ the temperature, m the mass of a gas molecule, and $\overline{u^2}$ the mean square velocity of the turbulence field.

First, we should like to point out that because of the slow change in density in this process, the temperature will not vary adiabatically, as in the case of the relatively high frequencies involved in most acoustic radiation, but rather will approximately obey a polytrope law of the form

$$\theta = \theta_0\left(\frac{\rho}{\rho_0}\right)^{\alpha-1}, \tag{2}$$

where α is adjusted to give the best fit to the theoretical equilibrium temperatures[3]. One finds approximately $0{\cdot}4 < \alpha < 1{\cdot}00$ in H_{I} regions and $1{\cdot}00 < \alpha < 1{\cdot}04$ in H_{II} regions. Thus γ should be replaced by α in equation (1).

Secondly, we should like to point out that expression (1) may be derived by some simple physical arguments. From the virial theorem one sees that it is the internal translational velocities of the molecules which oppose the gravitational forces. The kinetic temperature is defined as a direct measure of these motions. Thus, we define a 'turbulence temperature' Θ by

$$3k\Theta = m\overline{u^2}. \tag{3}$$

We also assume that

$$\Theta = \Theta_0\left(\frac{\rho}{\rho_0}\right)^{A-1}. \tag{4}$$

Now, without turbulence,

$$\lambda^2 = \frac{\pi k}{G\rho m}\,\alpha\theta,$$

so that $\alpha\theta$ is the quantity characteristic of the internal stability of the medium. To include the turbulence, therefore, we simply replace $\alpha\theta$ by $\alpha\theta + A\Theta$. We obtain

$$\lambda^2 = \frac{\pi k}{G\rho m}\,(\alpha\theta + A\Theta). \tag{5}$$

If we assume, after Chandrasekhar, that $\overline{u^2}$ is independent of time, while ρ is varying, then $A = 1$ and we have:

$$\lambda^2 = \frac{\pi k}{G\bar{\rho} m}\,(\alpha\theta + \Theta).$$

If $$c^2 \equiv \alpha\frac{k\theta}{m},$$

and is the velocity of sound with period less than the thermal relaxation time of the gas, then we may write

$$\lambda^2 = \frac{\pi}{G\bar{\rho}}\left(c^2 + \tfrac{1}{3}\overline{u^2}\right).$$

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, December 15

School of Pharmacy, University of London (in the Chemistry Lecture Theatre, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. C. D. Darlington, F.R.S. "Genetics and Medicine".*

Society of Chemical Industry, Crop Protection Panel of the Agriculture Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5 30 p.m.—Mr. H. E Harbour: "The Chemical Control of Animal Parasites".*

Tuesday, December 16

Society of Chemical Industry, Agriculture Group (in the Chemistry Lecture Theatre, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.15 p.m.—Dr. J. H. Hamence, Dr. N. H. Pizer and Dr G. W. Cooke: Papers on "The Determination of Phosphorus and Potassium in Acid Extracts of Soils".*

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 30 p.m.—Prof. Roger Russell "Experimental Studies of Hereditary Influences on Animal Behaviour".*

Oil and Colour Chemists' Association, London Section (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Dr. D. F. Rushman: "Radio-chemistry in Paint Research"

Tuesday, December 16—Wednesday, December 17

Association of University Teachers (at Trinity College, Cambridge).—Meeting of the Central Council.

Wednesday, December 17

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Rt. Hon. Lord Merthyr: "A Reformed Calendar".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Royal Meteorological Society (at 49 Cromwell Road, London, S W.7), at 5 p.m.—Scientific Papers.

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. Jean Hanson: "The Sub-Microscopic Structure of Muscles".

Institute of Fuel (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C 2), at 6 p.m.—Papers on "The Sulphur Content of the Flue Gases discharged from Power-Station Chimneys".

Thursday, December 18

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr N. S. Hawley: "Functions of Several Complex Variables".

Society of Chemical Industry, Microbiology Group (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 6.15 p.m.—Dr. Arthur Hughes: "Aspects of Cell Life—Behaviour of Embryonic Cells in Tissue Culture".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Prof. S. Sambursky: "Science in Israel".

Thursday, December 18—Friday, December 19

Physical Society (in the Physical Laboratories, The University, Manchester).—Autumn Provincial Meeting on "Ionization Loss by Relativistic Particles".*

Friday, December 19

Biochemical Society (in the Department of Biochemistry and Chemistry, St Bartholomew's Hospital Medical College, Charterhouse Square, London, E.C.1), at 2 p.m.—Scientific Papers.

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Brigadier R. A. Bagnold, F.R S: "Navigation on Land".

Saturday, December 20

Nutrition Society (in the Department of Biochemistry, The University, Sheffield), at 10 15 a.m.—Conference on "The Role of Vitamins in Metabolic Processes".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Botanist (male) (Pass degree in botany is essential) in the Field Investigation Department, to work on the determination of damage to grain and other seeds by mechanical harvesting—The Secretary, National Institute of Agricultural Engineering, Wrest Park, Silsoe, Beds (December 19).

Assistant Chemist at the Sewage Treatment Works, East Hyde—The Town Clerk, Town Hall, Luton (December 20).

Assistant Lecturer in Anatomy—The Secretary, University College, Gower Street, London, W.C.1 (December 20).

Principal Scientific Officer at the Propulsion Research Laboratory, Salisbury, South Australia, to be responsible for initiation and general supervision of research and development in the fields of general physics and instrumentation related to rocket propulsion research—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (December 20).

Lecturer and a Senior Lecturer in Anatomy—The Dean of the Medical College, St Bartholomew's Hospital, West Smithfield, London, E C.1 (December 31).

Principal Agricultural Economist and Head of the Agricultural Economics Department with the status of Reader—The Registrar, The University, Manchester 13 (January 13)

Science Studentships at the Military College of Science, Shrivenham—The Secretary, Ministry of Supply (Est 3 c), Room 510, Carlton Hotel, Haymarket, London, S.W.1 (January 14).

Agronomist (Ph.D. in agronomy, with specialization in soil fertility, is the minimum requirement)—The Secretary, Tobacco Research Board, P.O. Box 1909, Salisbury, Southern Rhodesia (January 15).

Chair of Physical Chemistry at the Institute of Cancer Research (Royal Cancer Hospital)—The Academic Registrar, University of London, Senate House, London, W.C 1 (January 15).

Senior Lecturer, a Lecturer, and a Fellowship (temporary), in the Department of Chemistry and Chemical Technology, University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 15)

Readership in Statistics at the London School of Economics and Political Science—The Academic Registrar, University of London, Senate House, London, W C 1 (January 20)

Chair of Electrical Engineering in Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 31)

Graduate Assistant (physiologist with knowledge of modern physical techniques, who would be interested in cardiovascular system)—Dr. G. S Dawes, Nuffield Institute for Medical Research, Oxford (January 31).

Lecturer in Civil Engineering at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 31).

Assistant Director of the Commonwealth Institute of Entomology—The Secretary, Commonwealth Agricultural Bureaux, Farnham Royal, Bucks (February 28).

Assistant Lecturer (with an honours degree and interested in the physical aspects of biochemistry) to teach Chemistry and Physics, and to co-operate in the research work of the Scottish School of Bakery—The Secretary, Royal Technical College, Glasgow.

Assistant Lecturer (Grade A) to teach Physical Chemistry to B.Sc. and A R I.C. standard—The Principal. School of Technology, Tower Ramparts, Ipswich

Biochemistry Graduate (Ph D.) with experience in the enzyme field, to collaborate on research on the enzymes of developing red blood cells—The Regional Director, Blood Transfusion Service, Royal Infirmary, Edinburgh 1.

Botanist to assist in the preparation of Flora of Tropical East Africa at Royal Botanic Gardens, Kew—The Under-Secretary of State, Research Department (S 610), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1

Demonstrator in Botany—The Registrar, The University, Nottingham

Mechanical and Electrical Engineers for design, operation and maintenance of ground mechanical and electrical works services on R.A.F. and Civil Aviation stations, home and overseas—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.290/52A

Mechanical or Electrical Engineer (with a first- or second-class honours degree in mechanical or electrical engineering) at a Ministry of Supply Design Establishment at Chertsey, to investigate vehicle ride performance, including experimental determination of component stresses as found in fast cross-country vehicles, and vibration and noise characteristics as obtained during road and rig tests—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W 1, quoting C.690/52A

Meteorologists in the East African Meteorological Department—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.57/88/01.

Physical Chemist or Engineer (with a first- or second-class honours degree, or equivalent, in chemistry or engineering) at the Royal Aircraft Establishment, Farnborough, to take charge of small section engaged on research and development work on manufacture and properties of reinforced plastics, with special reference to nature, production and properties of reinforced fibres such as glass and asbestos—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S W.1, quoting F.756/52A.

Plant Pathologist (with a degree in natural science with training in plant pathology) to investigate diseases of coffee at the Coffee Research Station, Ruiru, Kenya—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting 27059/197.

Regional Trials Officer (with a degree in agricultural or natural sciences, with practical experience in crop production) in charge of the Institute's trials in mid-Wales, a Senior Technical Officer (with a degree in agriculture or natural sciences, with suitable practical experience or postgraduate training in research) in the Seed Production Branch, to work mainly on root and vegetable crops, and a Technical Officer (with a degree in natural sciences or agriculture and, preferably with some practical or postgraduate experience) in the Crop Improvement Branch, mainly in connexion with the testing of plant-breeders' material at the Seale-Hayne Trial Station—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Senior Scientific Officer (with first- or second-class honours degree, and experience in organic chemistry or biochemistry) at the D.S.I.R. Food Investigation's Torry Research Station, Aberdeen, for work on the chemistry and biochemistry of extractives and volatile components in fish muscle that are responsible for flavour and odour in fresh, spoiling and cured fish—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.760/52A

INTERNATIONAL SCIENTIFIC RELATIONS AND NATIONAL SECURITY

AN important chapter in the Berkner report, "Science and Foreign Relations", issued in 1950 by the International Science Policy Survey Group of the United States Department of State*, considered the controls over the international flow of scientific information, from the point of view both of persons and of material. Earlier in this report, stress was laid on the positive contribution to the advancement of science, as well as to the security of the United States, which resulted from the full and free interchange of scientists and technologists and of information, as had been earlier emphasized in the Steelman report, independent of its reminder that national security depends far more upon the total scientific potential than upon anything else. Considering, however, the negative aspect, that of the types of control over such interchange which might be desirable from the point of view of security, the Survey concluded that there was ample evidence that unnecessary restrictions existed on the flow of unclassified scientific and technological information, and that these restrictions were dangerous to the progress of science in the United States, affected adversely the conduct of foreign relations in science, and were therefore damaging to national security.

This Berkner report pointed out that visa regulations and their restrictive effect on proposed visits to the United States by foreign scientific men involved for any particular case a balance, within the limits of the immigration statutes, between considerations of security and other national interests, including considerations of international scientific relations. Unless, however, foreign scientists were permitted access to their American colleagues, either at international meetings or through individual visits, science in the United States lost the benefit of the potential contribution of foreign research and technical advances to its own. The Berkner report made no specific recommendations for change in practice: it was content to point to the dangers of the situation, particularly that of the creation of a furtive atmosphere in which the flow of information necessary to progressive science was halted. It did, however, also stress that the relation between internal security and exchange of technical information represents a balance of interest similar to that required in the visa situation. The conclusion was reached that no definite and positive controls of unclassified technical information are possible under the American system of government, and that it would be inimicable to the American way of life to attempt to control the use of information that is freely available to everyone. From this point of view it is asserted that the Department of State has a special responsibility for bringing to the attention of the Interdepartmental Committee on Internal Security the implications of security situations which adversely affect international scientific relations.

---

* United States Department of State Publication 3860: Science and Foreign Relations. (General Foreign Policy Series 30.) Pp. viii+170. (Washington, D.C.: Division of Publications, Office of Public Affairs, 1950.)

Since this report was issued, several books have been published in which the whole question of secrecy and security regulations as it affects the progress of science has been discussed. The misgivings freely expressed by American scientific men regarding the procedures and practices current in the United States have frequently been framed in general terms which could be emphatically endorsed by their colleagues everywhere in the free world. It has been made abundantly plain that in their protests against the absurdities and excesses to which security regulations and procedures have been carried in the United States, American scientific men and other scholars have stood firmly and responsibly on those principles of intellectual freedom of investigation, of utterance and communication, which were written into the constitution of their country and are the fundamental condition of scientific advance.

Something less than justice has been done, on the whole, to the stand against the threat to intellectual freedom which has been made by men of science in the United States, both within and without the universities. That is one reason for welcoming the special issue of the *Bulletin of the Atomic Scientists* (8, 209; Oct. 1952), which is devoted to American visa policy in its relation to foreign scientific workers. Ultimately that policy, whatever its effects, is a matter for American scientific men and their fellow citizens, and there are details on which comment from outside would rightly be resented. The experiences of British, French and other European scientific men narrated by the individuals directly concerned are indeed purely factual, and in their range they show clearly the extent to which the policy is of international concern and is handicapping scientific work and communication generally. The survey includes the text of the relevant passages of the Internal Security Act of 1950, generally known as the McCarran Act. American comments are often critical but also constructive, recognizing as clearly as Prof. A. V. Hill, in his presidential address to the British Association, that complete abandonment of secrecy is out of the question and that some measures of control in the interest of security are inevitable. But this indictment by American scientific men and other scholars of their Government's policy and its execution cannot be read outside the United States without recognizing the courage and honesty required, in present circumstances, of those who framed it.

Any foreign comment on this issue must start by way of tribute to that courage and sincerity. That alone should dispose of any fear expressed by Prof. E. A. Shils in his editorial, "America's Paper Curtain", that this exposure will do more harm than good. Attempts to use such material against the United States are out of the question while it remains manifestly impossible for any corresponding protest against government restrictions or policy to be voiced behind the Iron Curtain. Against such risks the issue seems admirably designed to promote that formation of enlightened American public opinion which is the essential preliminary, either to the wiser execution of the present policy or to its modification in the direction they indicate.

Prof. Shils, in this editorial, points out that the survey has been confined almost entirely to scientific workers, with three illustrative instances from other fields of learning. It includes an account from Prof. L. Pauling of the Department of State's refusal of his request for a passport last February and its ultimate issue in July more than two months after the Royal Society discussion which he had originally proposed to attend. Prof. Shils comments that Prof Pauling's statement shows that the fundamental errors of the present policy are not due to legitimate concern with security, but are the manifestations of an underlying xenophobia and of an undue sensitivity to criticism. He is concerned that the refusal to allow foreigners to discuss unclassified scientific matters freely with American scientific men, and efforts to prevent American scientific men with no classified information from going abroad to meet European men of science, falsify the United States' claim to leadership in the defence of the free society of the West. Prof. Shils touches briefly but adequately on the more personal consequences of delay or refusal to issue a visa, against which it was necessary some years ago to protest in Great Britain also (cf. *Nature*, 156, 215; 1945). Any strain which he fears the present American policy is likely to place on the faith of overseas men of science in the soundness of a common cause with the United States should, however, be more than eased by the dignified protests made by Prof. Shils himself and by his fellow citizens such as Dr. A. Einstein, Prof. H. A. Bethe, Prof. H. C. Urey, Prof. J. Franck, Dr. A. H. Compton, Dr. W. P. Murphy and others. Incidentally, this number should remove any misgivings as to the attitude of American men of science that may have been read into Dr. D. W. Bronk's address to the British Association in Belfast last September.

Prof. Shils's argument is, however, mainly that the McCarran Act impedes American efforts to block the Communist attempt to dominate the mind of Europe and to break the North Atlantic Treaty Organization, and that it also weakens the security of the United States itself. International scientific organizations, he points out, are already beginning to avoid arranging meetings in the United States with a loss to science in the United States which no expenditure or apparatus can replace. Free informal contact, the exchange of impressions and interpretations, and the comparison of results and procedures in face-to-face conversations retain all their advantages and are indispensable.

These points are reiterated in a report prepared by a Committee of the Federation of American Scientists of which Prof. V. F. Weisskopf was chairman. The report, however, merely makes the points that the present visa policy is contrary to the fundamental principles of American political philosophy, that it is harmful both to science in the United States and to scientific life in Western Europe and that it is seriously weakening the position of the United State abroad: no concrete proposals are advanced, however, for the revision of the Internal Security Act and the Immigration and Nationality Act, both of which, it may be recalled, were vetoed by President Truman and sustained by Congress over his veto. Prof. Shils, after remarking on the need for consular officers responsible for decisions about visas to be more realistic and better informed, makes several definite suggestions, which in essence amount to a plea for a return to common sense and to common humanity which might be noted and heeded in other countries besides the United States. In particular, Prof. Shils suggests that the law should be changed so that those who have not been members of Communist groups for the past five years should be able to enter the United States for scientific purposes; and he protests against the absurdity of applying the same rigorous criteria to a visitor for a few weeks or months as to a prospective permanent resident or citizen, as is done by the present law. Equally he argues for a more particularized defence against alien subversives and less diffuse fear of foreigners and of scientific men. Both the law and legislators should permit administrators to free their minds from the constant and obsessive pre-occupation with Communist subversion whenever they deal with a foreigner or a scientific worker. Consuls should be given discretionary powers to grant, as well as to refuse, visas, and be expected to use them.

The most encouraging feature of this review is the emphasis on positive measures. It is recognized that full provision must be made for counter-intelligence and security services. No countenance is given to the doctrine, which was condemned forthright by Prof. A. V. Hill, that the freedom of conscience, which is the first condition of freedom, for the scientist as for any other citizen, extends to the giving away of other people's property, whether of goods or knowledge. Implicit in the survey is the belief that scientific men are loyal and can be trusted, and the whole issue may be taken as a considered attempt to dispel the distrust of the educated and the suspicion of the scientist which are clearly preventing the reasonable working of even existing regulations and policy.

The existence of certain anti-scientific trends, which are partly responsible for the present timidity of consular officials in granting visas, is as manifest in this survey as in the address on that specific subject which Prof. Kirtley F. Mather delivered at the annual meeting of the American Association for the Advancement of Science in December 1951 (see *Science*, 115, 533; 1952), and is indeed one reason why this issue of the *Bulletin of the Atomic Scientists* is of general interest. These trends are not confined to the United States. They are to be found in Britain also and are of increasing importance as the dependence of scientific research upon public funds for support rather than upon independent or private endowments continues to grow. They are responsible, too, for the misunderstandings and uninformed judgments which sometimes hinder the furtherance of scientific work in Great Britain.

Prof. Mather, like Prof. Hill, sees that in the practical world of to-day complete abandonment of secrecy, in government and in industry, is out of the question. The limits of such secrecy have to be determined as a matter of practical policy by honest and courageous effort, and the first steps in that direction for American scientists have been indicated by Prof. Mather and now by Prof. Shils and others.

These measures have their implications for scientific men elsewhere. It is not sufficient to acknowledge the courage displayed in these protests against illiberal practice and policy. The convictions on which they are based are shared by men of science everywhere, and the Jefferson dictum quoted by Prof. Mather, "We are not afraid to follow truth wherever it may lead, nor tolerate error as long as reason is left free to combat it", echoes the earlier words of Milton: "who ever knew Truth put to the worse in a free and open encounter?" And men of science in Great Britain too must realize, as Prof. Hill reminded them, that the prestige of science is not their personal property, but a trust which they have an obligation to pass on uncompromised to their successors.

This issue of the *Bulletin of the Atomic Scientists* represents, in fact, a step in a campaign of public education directed specifically, as Prof. Mather suggested, against what appears to be a well-organized attempt to paralyse all independent thought, discussion, dissent and protest in the United States. The extent to which in recent Parliaments in Britain independent opinion has been excluded is sufficient reminder that a like danger exists here also, and that British scientific workers must take their share in the task of educating public opinion as to what is required if a free society is to continue. Neither science itself nor a free society can long flourish in the climate of fear and negation against which this American protest is directed.

To place confidence in scientific security is, as Mr. H. A. Wallace told President Roosevelt's Cabinet, to rely on the imagined security of a Maginot Line. Only such a dynamic and positive policy as the Steelman Committee visualized can provide an adequate basis for security; but to achieve such a policy demands both public understanding of the nature of scientific and technological advance and confidence in the scientist and technologist. With the work of education involved in this first task must go an attempt to repair whatever shocks public confidence has undoubtedly received from recent episodes. This question of professional loyalty seems to be worth a little closer attention by professional bodies, as indeed seems to be implied by Prof. Hill's remark in his presidential address to the British Association; and while it may be of some interest and profit to discover the real causes of the exceptional failures in loyalty, whether to a professional tradition or scientific discipline or to a community, it is imperative to satisfy the community of the basic loyalty of the overwhelming majority of scientists and technologists.

That is one step towards establishing the full understanding and confidence which can deprive present anti-scientific trends of their real power. Clearly it is one which could well be taken even more effectively by joint action between British and American men of science, as was indeed suggested by Dr. J. B. Conant in his Stevenson Memorial Lecture last March. It is perhaps curious that this issue of the *Bulletin of the Atomic Scientists* is so preoccupied with the exclusively American aspects of visa policy that no attention is given to the wider aspect of the secrecy question and the suggestion for Anglo-American co-operation made by Dr. Conant. It may be hoped, however, that this indication of the extent to which scientific opinion in the United States and in Britain is in line on the issue of the interchange of knowledge and the problem of secrecy in relation to security will give a fresh impulse to a co-operative attempt to find a satisfactory solution to problems as yet unresolved in either country, which in essence are a particular aspect of the general one of power and responsibility. As Dr. J. Bronowski insisted at the Present Question Conference in 1951, it is a responsibility of the scientist to-day to become a teacher to the whole community, so that society learns to understand the implication of his work. Only when that task is discharged with imagination can society wisely exercise its own responsibility, directing its policy towards ends which turn to good, and entrusting the execution of its policy to those who will do so with courage and with wisdom.

LINNÆUS REDIVIVUS

Carl Linnæus

By Knut Hagberg. Translated from the Swedish by Alan Blair. Pp. 264+4 plates. (London: Jonathan Cape, Ltd., 1952.) 18*s*. net.

Svenska Linné-Sällskapets Årsskrift

Arg. 33–34, 1950–51. Pp. iii+188. (Uppsala: Almquist and Wiksell, 1951.)

ACCORDING to the publisher, inspired doubtless by the author himself, this work has not been written for the specialist, nor does it aspire to be a normal biography following traditional lines. Rather is it an analysis of the outstanding personality of the "greatest rational and consistent scientific genius that Swedish cultural history has known". It is claimed that Linnæus was not only a great botanist, but also that he excelled as a philosopher and a master of his own language, whose purpose it was to standardize a system of botany consistent with a designed and orderly creation by the Deity. This, says Linnæus, was possible by a study of Nature herself, but was not deducible from books.

Knut Hagberg's restrictions of the scope of his work are not always conducive to a just understanding of Linnæus's contributions to biology. Thus, in the section on "Floral Nuptials", the lay reader will not be able fully to assess Linnæus's attitude towards this very important matter, nor will he gather what was his contribution to the discovery of the facts and the part he played in accepting and exploiting them in his schemes of classification. It is to be noted that Sachs, a great and not always a just and fully informed critic, while asserting that Linnæus added nothing new to the sex theory of plants, allows that he contributed essentially to its recognition, and thus acquires an overwhelming importance for the skilful way in which he gathered up all that had been done before him and fused together the scattered acquisitions of the past. This, Sachs concludes, is the great and characteristic merit of Linnæus. It is unfortunate, as Hagberg regretfully admits, that "Linnæus would never have admitted his debt to a predecessor. Such was his disposition and we must bear with him".

Linnæus's study of Nature exposed some startling and distressing anomalies, which he accepted without attempting to explain, or even realizing that some explanation was expected of the philosophic naturalist. For example, in his paper on the 'gadfly' (= warble fly, *Oedemagena tarandi*), which attacks the reindeer, he is full of admiration for the skill exhibited by the Creator in adapting the insect to a complex life-history of merciless parasitism, but has no thought or pity for the miseries endured by the tormented reindeer, which, none the less, he describes in detail. Such examples of the ruthless struggle for existence, in which he believes that some species have been specifically created for the torment and destruction of others, appeal to him only as glorious spectacles of the wisdom of God, and he views with reverent but unsympathetic enthusiasm the existence of poisonous snakes as masterpieces of the wonderful power of the Creator. He had evidently no conception of the possibility that inflexible natural laws, acting mechanically on plastic material, would produce a fortuitous medley of living organisms.

The views of Linnæus on evolution begin in 1751 with the statement of 'fact' that the number of species now existing is the same as that created at the beginning of the world. Later, however, he came to accept that species and genera were the products of time, but continued to hold that the natural orders were the works of the Creator. This does not mean that he had hit upon the idea of evolution, since he maintained that the emergence of new forms would of necessity result from the incidence of cross-breeding. However, albeit with some reluctance, he no longer denies that new species have, in fact, arisen in time. This marks the complete abandonment of his original conception of species. What he considered he had discovered was the *plan* of the creation. To quote his own words: "God has suffered him to peep into his secret cabinet. God has suffered him to see more of his created work than any mortal before him. God has endowed him with the greatest insight into natural knowledge, greater than any has ever gained. The Lord has been with him, whithersoever he has gone, and has exterminated all his enemies for him, and has made of him a great name, as one of the great ones of the earth". Hagberg's comment on such naive and frank manifestations of our egocentric is: "Linnæus was not one of those who doubt themselves or the significance of their achievements. It would be hard to find more unstinted admiration of his importance than that he himself expresses in many places . . . the thought is always there that God's blessings towards him have indeed been justified".

There are many passages in this original and deeply interesting study which would call for notice if space were available, but a few others need revision or correction. Among the latter is the statement that Thomas Bewick owes something to the literary style of Linnæus. The text of Bewick's works was written by Ralph Beilby, except that, when Beilby broke away from the partnership, Bewick had to write the text of Part 2 of the "Birds" himself. He did this of necessity and with many misgivings, and it is difficult to discover in the result any traces of the influence of Linnæus. Again, Hagberg's description of Clerck's work on Swedish spiders as a "lovely book whose pictures are an abiding source of joy" makes one wonder whether he is acquainted with those classic illustrated texts of zoological literature to which alone such an encomium can reasonably be applied.

The lack of an index is to be regretted.

F. J. COLE

THE IRIS IN THE SOUTHERN HEMISPHERE

The Iris and Its Culture

By Jean Stevens. Pp. 168+20 plates. (Melbourne and Sydney: Lothian Publishing Co. Pty., Ltd., n.d.) 45*s*.

IN Britain lovers of the iris are generously provided with works of reference. Apart from W. R. Dykes's large monographic study of the genus, still the standard work and long likely to remain so, there are his shorter works and numerous papers on the culture and breeding of these plants, and, as recently as 1950, Mr. N. Leslie Cave's very informative and practical handbook. The needs of American iris growers in large measure have been met by the American Iris Society's publication in 1947 of a comprehensive treatise, "The Iris, an Ideal Hardy Perennial", and by the late Prof. Sydney Mitchell's "Irises for Every Garden".

No such works have been available for growers of the iris in the southern hemisphere, where, because seasons and conditions, and consequently horticultural practice are so different, growers cannot use profitably much of the information contained in books concerned with culture in the northern hemisphere. Thus an authoritative statement, especially a cultural statement, on this genus as it is grown in New Zealand and Australia has long been desirable and at last has been made by Mrs. Jean Stevens, the federal president of the Australian and New Zealand Iris Society and the first president of the New Zealand Iris Society, and who for more than twenty years has been a successful cultivator of the numerous species of this genus, and a noted breeder with an international reputation of the more numerous garden hybrids, especially the tall bearded irises.

"The Iris and its Culture", therefore, is the first handbook on irises to be written for gardeners in New Zealand and Australia, and as such it is eminently suited to its purpose. One half of the book is devoted to a classification of the genus and to a description of the various species from a horticultural point of view. In a country such as New Zealand where, apart from privately owned copies, Dykes's monograph apparently is available only in the County Library Service in the South Island, specific descriptions of some kind obviously are essential. These descriptions, however, are no mere rehashes of those of Dykes, but are written from personal observation and experience, for the author has grown and flowered almost all the species discussed. As a result of the information of intense practical value which is woven into this enumeration of the species in their various groups, readers will not be tired and irritated (so often the reaction of the practical gardener to species descriptions) by this section of the book.

The rest of the book—the first seventy-five pages—in the main is concerned with the history, breeding and cultivation of the hybrid bearded irises which have been bred for more than a century, have been popular with many growers for some twenty to twenty-five years and which, due to their vast improvement in colour, form and substance, during the past ten years or so have rushed meteorically to the forefront of gardening in both hemispheres. Because most of the emphasis on iris growing to-day is on the bearded irises, and because Mrs. Stevens can speak authoritatively (she is recognized as one of the foremost breeders of bearded irises in the world, and with her irises Pinnacle and Summit has raised the first white and yellow bicolours – white standards and yellow falls), one does not feel that to devote one half of the book to this group of plants is to give them much greater prominence than their position in the genus merits. The reviewer does feel, however, that the author could have elaborated her two chapters on the breeding of the bearded irises to the extent of introducing and explaining such terms as diploid, tetraploid and polyploid. By so doing, the true significance of the year 1900 in the evolution of the tall bearded iris could have been made plain. All hybrid bearded irises raised up to 1900 were diploids, and their parents were the tall-stemmed blue-violet flowered *Iris pallida* from Dalmatia and the short-stemmed yellow flowered *I. variegata* of the Balkans, and some of their natural hybrids such as *I. squalens*, *I. neglecta*, *I. plicata*, *I. amœna*, etc. In 1900, the Asiatic species *I. cypriana*, *I. trojana* and *I. mesopotamica*, all large-flowered and tall-growing, and all of them tetraploids, were introduced into Britain and were used more and more in breeding. As a result, by 1915, 33 per cent of the hybrids in Britain were tetraploids; by 1920, 45 per cent were tetraploids; by 1930, 75 per cent were tetraploids, and by 1940 there was scarcely a diploid tall bearded iris.

As for the illustrations of Mrs. Stevens's book, only some of the sixteen monochrome plates are good, and even though the best of them give some indication of the colour patterns of the flowers, none gives any idea of the actual colours or of the flower texture. More colour plates of the calibre of the frontispiece illustrating many of the colour forms of *I. innominata* or of *I. gracilipes* would have enhanced the book greatly—though perhaps at the same time have increased considerably the published price, which even at 45*s*. those in Britain who are interested in the genus are likely to regard as somewhat prohibitive.

H. R. FLETCHER

ANTHROPOLOGY DURING THE PAST CENTURY

A Hundred Years of Anthropology

By T. K. Penniman; with Contributions by Beatrice Blackwood and Dr. J. S. Weiner. (The Hundred Years Series.) Second edition, revised. Pp. 512. (London: Gerald Duckworth and Co., Ltd., 1952.) 30*s*. net.

THIS work is up to p. 344 a reproduction of an earlier work which was first published in 1935. The publisher's claim printed on the dust-cover that it reappears revised is not confirmed by the author, who speaks of photographic reproduction with minor emendations. There remain to review here its final pages, which discuss the subject of anthropology since 1935.

The section on prehistory and technology in the Old World, pp. 345–375, records considerable progress in Near-Eastern archæology since 1935, gives an account of the titles of the main works concerned and sometimes adds a few sentences indicating the general nature of their contents. There are interesting accounts of methods employed in dating archæological discoveries. The author only lapses into speculation, however, when he suggests that, if all modern inventions were lost, those made in the Near East about the fifth millennium would still make the good life possible, and when he asserts that prehistoric art was done partly for art's sake and partly to aid the artists to control the incalculable in life.

There follows a survey of physical anthropology since 1935 written by J. S. Weiner (pp. 376–412). Weiner mentions, among other matters, that it still remains for the physical anthropologist to demonstrate in the field how the biological properties of a community and its social organization are interrelated. He tends to over-emphasize the comparative importance of the study of discontinuous variation, on the grounds that the gene systems underlying blood groups are known, whereas the study of continuous variation by 'traditional' anthropometric measures uses phenotypic criteria the genetic bases of which are unknown.

Miss Beatrice Blackwood gives an account of Americanist studies (pp. 412–40), which is adequate except that it omits sociological and psychological studies of the American Indian from review, and refers the reader to a bibliographical paper published elsewhere for titles of such studies.

The final fifteen pages of text on general ethnology and social anthropology list some titles of books, and lay disproportionate stress upon such purely occasional papers as a bibliographical Americanist paper by Betty Meggers and a chapter in "The Development of Scientific Thought in the Twentieth Century", edited by A. E. Heath, by Meyer Fortes. The works of Margaret Mead, which are internationally known for their value, are not mentioned. Otherwise these pages are mainly concerned with a difference of opinion of small importance between Radcliffe-Brown and Evans-Pritchard. Radcliffe-Brown considers that sociology will yet become a natural science; Evans-Pritchard points to an absence of laws of social organization discovered to date, represents himself as a "functionalist seeking a new orientation", and in common with Radcliffe-Brown ignores the possibility of knowledge of social psychology. There is a long résumé of a single lecture by Evans-Pritchard, but the works of Peristiany, Nadel, Gluckman, Hunter, Kuper, Godfrey Wilson, Hallowell, Embree, Oliver and many others are completely overlooked. Since there is no evidence of similar loss of proportion or failure of good judgment in the preceding three sections of the book reviewed, the author's more than ordinary concern here that the works of a few persons now or recently at Oxford should be given such prominence is all the more remarkable. The result is not a judicious appraisal.

About psychological studies, it has been said that anthropologists who discuss topics of the nature of motivations and attitudes attempt to explain social phenomena in terms of individual psychology; but the social anthropologist and the psychologist study different kinds of phenomena—the former social systems, and the latter psychical systems—and what one studies cannot be understood in terms of conclusions reached by the other. It has also been said that those who study topics of the nature of motives and attitudes avoid the real work of ethnology as drastically as those who study nothing but social organization, and explain what they study in terms of the functional efficiency of organization in maintaining itself. These criticisms are actually not substantial, since knowledge of any still-existing society depends absolutely upon knowledge of individuals who are in that society or who share that culture. The ethnological or social anthropologist critic owes his own knowledge of still-existing peoples to the study of individuals in disregard of antitheses between individual and society, organism and environment, personality and social structure, at least until the last minute when he begins to write down what knowledge he possesses. R. F. FORTUNE

EXPERIMENTAL METHODS IN ARABLE HUSBANDRY

The Practice of Arable Crop Experimentation

By P. N. Harvey. Pp. vii+79. (Norwich: Norfolk Agricultural Station, Sprowston, 1952.) 6s.

IN the literature of agricultural experimentation the statisticians are much more in evidence than the field workers; but no matter how ingenious and adequate statistical methods may be, their practical value in dealing with agricultural problems largely depends on the common sense and skill of those who handle the experimental operations on the farm. As soon as crop trials became something more than rough yield comparisons between treated and untreated halves of the same field, some sort of technique became necessary, and this has been developed during the past thirty years both to meet the needs of the newer experimental designs and to reduce working errors. The people responsible for this have been the field supervisors and farm managers of experimental farms, with the statistician available to advise on matters of principle. The methods developed, although recorded in scattered memoranda and papers, have not been widely published, and it is here that Mr. P. N. Harvey's book makes a useful addition to the literature.

The Norfolk Agricultural Station at Sprowston was well established when the new experimental designs began to be introduced in the early 'twenties, and it was quick to adopt them in its studies of crop husbandry. Mr. Harvey puts on record the field methods that have been gradually built up and developed at the Station for experiments on arable crops. The operations are described in detail with the drawings that are necessary to make the procedure intelligible. The subject-matter covers the choosing of land, the marking out and sowing of plots, and the harvesting and sampling of cereals and roots. The procedure adopted for harvesting plots by combine, a recent development of great promise, is dealt with at length. There are also sections dealing with the application of fertilizers and the calibration of seed and manure drills

There is no finality in these methods, and field experimenters, now an increasing company, are recommended to read this book, for it will provide a basis on which to review and, in many instances, to improve their own procedure. For students it is an excellent introduction to the subject.

ACCURACY AND SENSITIVITY OF THE HUMAN EYE

By Dr. M. H. PIRENNE and Dr. E. J. DENTON

Physiology Department, Marischal College, University of Aberdeen

It is well known that the sensitivity of the human retina is so high that a few quanta absorbed by the retinal photoreceptors can initiate a visual response[1–4]. We wish to show here that this finding, obtained in special laboratory experiments, is also valid for ordinary vision over a wide intensity-range up to daylight intensities sufficient to give accurate form vision. In this range the finest details visible are almost as fine as they could possibly be in terms of the amount of light absorbed by the photoreceptors. Visual acuity and retinal sensitivity are here linked together, reaching almost to the natural limit set by the quantum properties of light.

A large continuously exposed field, emitting light of wave-length 0·51 μ, can just be seen by the dark-adapted eye when it produces[5] a retinal illumination of about 30,000 quanta cm.$^{-2}$ sec.$^{-1}$. (This and all subsequent values for retinal illumination are uncorrected for the light losses in the eye media, the extent of which is not known with a high degree of certainty[7].) The above illumination corresponds approximately to one quantum striking a given rod on the average every 1,000 sec., a fine retinal rod (or central foveal cone) being 2–2·5 microns in diameter[8].

It follows that, at an intensity-level 10^5 times above threshold, about 100 quanta strike a given receptor, rod or cone, every second. Only a fraction of such quanta are absorbed by the photoreceptors. Absorption by visual purple, the visual pigment in the dark-adapted rods, is probably of the order of 10 per cent. In the case of the cones, about the pigment of which little is known, it is generally believed that the absorption is lower than, or at the most equal to[8], that in the rods. Thus at an intensity 10^5 times threshold a rod absorbs about 10 quanta per second, a central cone possibly less. Therefore, as Baumgardt[9,10] has emphasized, even at high subjective levels of illumination, we are dealing with chemical reactions of a very special kind, the photochemical side of light-adaptation due to the bleaching of visual pigments being probably unimportant since the number of quanta absorbed is so small in comparison with the number of pigment molecules in the photoreceptors.

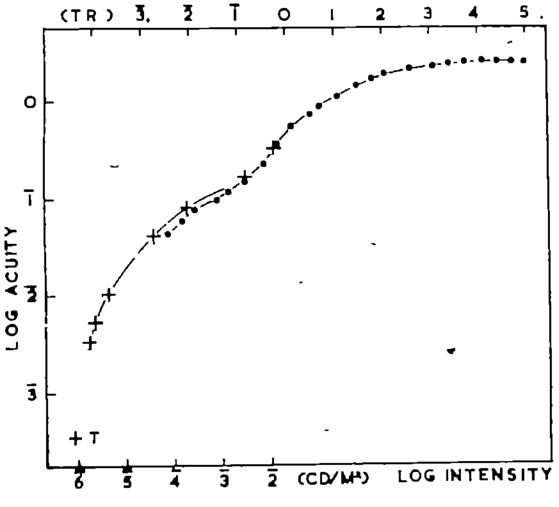

Fig. 1. Variation of visual acuity with light intensity. Acuity and intensity are both plotted on logarithmic scales. The upper scale gives the retinal illumination in trolands. One troland (0 on the log scale) corresponds to about 20 quanta of the most effective wave-length striking a retinal area 2 microns in diameter per sec. The lower scale gives the field intensity in candles per square metre. The point *T* represents the threshold intensity for a field 50° in diameter. The lower part of the curve up to about 1̄ (tr.) corresponds to peripheral (rod) vision; the upper part, from 0·5 (tr.), to foveal (cone) vision; the intermediate region to parafoveal vision. (+, unpublished measurements by M. H. Pirenne; ●, measurements by Shlaer, ref. 11)

Change of Visual Acuity with Intensity

With increasing light intensity, the ability of the eye to distinguish detail generally increases until it reaches a maximum value. Fig. 1 shows the results of experiments upon visual acuity made using black Landolt test objects (Fig. 2) upon an illuminated background. Visual acuity is defined as the reciprocal of the angle, in minutes of arc, subtended at the eye by the gap *a* of the smallest Landolt C which can be discriminated.

At any given illumination it is possible to calculate, from the data given in Fig. 1, the number of quanta which fall per second into the retinal image of the gap *a* of that Landolt C which can just be discriminated. For example, when the visual acuity is equal to unity, the gap *a* subtends an angle of 1′ at the eye, the retinal image of *a* is 4·85 μ square, the minimal illumination necessary is about 130,000 times the absolute threshold, and the retinal area corresponding to *a* receives (for the most effective wave-length) about 900 quanta per second. The results of similar calculations are tabulated in the accompanying table.

It is seen that for a wide range of acuities, from 0·01 to 1, and of intensities from 5 to 10^5 times the absolute threshold, the intensity of light striking the retinal image of the smallest detail detectable is of the order of 140–900 quanta per second.

Now the retina does not sum up the action of light over long exposures like a photographic plate. There

Acuity	No. of quanta falling into the gap *a* per sec.
0·003	1,200
0·01	270
0·03	138
0·1	270
0·3	780
1·0	890
1·6	2,240
2·0	5,600
2·4	120,000

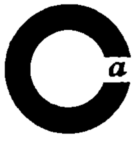

Fig. 2. Landolt test object. The letter *a* is added here merely to designate the gap in the broken ring; test objects used for acuity measurements do not contain it

is a maximum duration over which such summation can take place. For small areas in the periphery, the 'retinal action time' corresponding to complete physiological summation is about 0·1 sec. For larger areas it is shorter; but it is followed by an important period of incomplete summation[12]. For cone vision, the action time is apparently shorter than for the rods[13]. The value 0·1 sec. may thus be taken as an estimate of the retinal action time. In this connexion it will be borne in mind that, in the normal use of the eye, the eyeball moves in saccadic fashion, the retina generally taking a succession of discrete 'snapshots'[14,15] each with an exposure of the order of 0·2 sec.

Taking 0·1 sec. as unit time, the values of the amounts of light striking the gap *a* become 14–90 quanta. Now, experiments performed under special conditions by Hecht, Shlaer and Pirenne showed that, in order to be just visible to the dark-adapted subject, a flash of light must contain a nominal number of quanta of about 100 (54–148 quanta, at the cornea, depending on the subject[1,2]). The light, of wave-length 0·51 μ, was made to fall in the peripheral retina, 20° from the fovea, and came in a 0·001-sec. flash, from a test field subtending 10′ at the pupil. According to the experiments of Graham and Margaria[12], made 15° from the fovea, the threshold value, using the same time of exposure, would be almost the same for larger fields, up to 1° in diameter. For a 10′ field and a 0·1-sec. flash, the number of quanta necessary would be about 150; for 1° and 0·1 sec. it would rise to about 200. The quantities of light striking, per retinal action time, the retinal image of the smallest detail detectable, are therefore of the same order as those corresponding to the absolute threshold measured with a flash at the cornea of the eye. (They appear to be somewhat lower than the quantities corresponding to a flash, but the accuracy of the present calculations is not sufficient to prove that this difference is genuine. The upwards trend from acuity 0·01 to 1 in the values of the second column of the table should be regarded with the same caution.) We may conclude that the part of the retina receiving the image of the gap *a* can scarcely be excited above its absolute threshold under the conditions considered here. In the flash experiments, on the basis of various direct and indirect calculations, it is generally taken that the minimum number of quanta which must be *absorbed* by the retinal receptors for a threshold stimulation lies between 2 and 10 per flash[1–4]. Similar numbers of quanta must be absorbed here by the receptors receiving the image of the gap.

These calculations would be seriously in error only if effective light absorption by the cones were markedly higher than by the rods, which seems very unlikely. At the present stage, however, particularly because the properties of the cones are still imperfectly known, it is scarcely possible to determine the exact intensity-level at which the absolute threshold of the region corresponding to *a* is definitely passed. At the highest intensities, acuity is limited by other factors, including the wave properties of light[11,16].

Retinal Units

It would be impossible for each rod and each cone to act as an independent retinal unit, because the number of rods (120 million) and of cones (6 million) greatly exceeds the number of independent paths available in the optic nerve (1 million nerve fibres)[17,8]. It is known from anatomical studies that the retina contains bipolar or ganglion cells making connexions with greatly varying numbers of receptors, from tens of thousands of rods in the periphery to single cones in the fovea[18,19]. In many cases, rods and/or cones must function as compound units connected to one optic nerve fibre, as observed electrophysiologically in animal retinae[20–23].

Now, at a given level of illumination the areas of the retinal units used for discriminating a Landolt C cannot have diameters much greater than the size of *a*, the gap in the C which can just be discriminated. Otherwise the shape of the ring itself, the diameter of which is only 5 × *a*, could not be seen, whereas it is found that the shape of the ring always becomes visible at an intensity less than that necessary to see the gap. Since the retinal image of the just discriminated gap becomes smaller with increasing intensity, and since the size of the functional units must approximate to the size of this image, it follows that the retina must work in smaller and smaller functional units as the retinal illumination increases. It is known that the region giving the most accurate vision of detail shifts from the periphery to the parafovea and then to the fovea as the light intensity increases[11]. This is a movement to areas of the retina containing receptors organized in progressively smaller groups[18,19].

The following general explanation suggests itself. The sensitivity of the smaller units is lower in terms of retinal illumination because they are made up of fewer receptors, and perhaps because their constituent receptors (cones) are less sensitive. At any given intensity that retinal region is chosen which provides the finest mosaic of retinal units capable of working at this intensity. If the intensity were higher a mosaic of smaller units would be active in a more central region of the retina; but at the level considered, these units are not functioning because their absolute thresholds are not reached.

Organization of the Retina

Even in a given, constant, region of the retina, visual acuity increases considerably with increasing intensity, until it reaches a maximal value characteristic of the region chosen. Now, every retinal region contains ganglion cells connected to varying numbers of receptors and thus forming retinal units of various sizes[18,19]. Here, again, it is reasonable to think that the increase of acuity is due mainly to the coming into play of smaller and smaller units. Further, it is likely, because the threshold values are so low, that all the receptors are shared in common by functional units of different sizes. The following theoretical scheme gives a concrete illustration of this idea; to simplify the argument, only two groupings of rods are considered (Fig. 3). Consider 40,000 neighbouring rods connected to one single ganglion cell and optic nerve fibre. These rods form

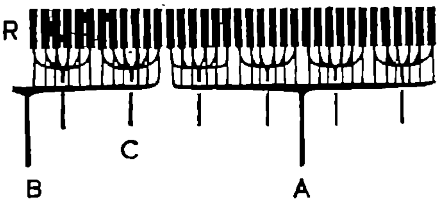

Fig. 8. Diagram of suggested retinal connexions. A large functional unit, *A*, and part of another, *B*, are shown. The same receptors *R* which form *A* and *B* are also connected in a different way to form smaller units such as *C*. At sufficiently high intensities, the small units absorb enough quanta to respond ; but at low intensities they do not, only large units summating enough light to remain active

one functional unit about 0·6 mm. in diameter on the retina, subtending a visual angle of 2°. Suppose the same group of rods is subdivided into 100 groups of 400 rods, each group being again connected to a separate ganglion cell and nerve fibre. In order to stimulate either the large unit or any one of the small units, a minimum of 6 quanta must be absorbed in the corresponding receptive field during a retinal action time of 0·1 sec. When the mean total number of quanta absorbed by the large unit is, for example, 10 quanta, the threshold of this unit will generally be passed and the unit will be active. But the small units then receive only an average of 0·1 quantum each, and remain generally inactive. If the retinal illumination is increased 100 times, however, the absolute threshold of the small units will be reached. Thus, without any switching mechanism to change nervous connexions in the retina, a finer mosaic of retinal units will automatically come into play when the intensity is increased.

At intensities near the absolute threshold for large fields, only the largest peripheral retinal units, which are indeed of the order of 2° in diameter[24-27], can be excited. Moreover, there must be a lower range of intensities in which even they are not all excited[28], since there is an intensity-range over which it is uncertain whether a retinal unit will respond or not. This uncertainty is an empirical fact of observation ; it is explainable to a large extent on the basis of the purely physical fluctuations of the stimulus itself, but there may also be biological variations of sensitivity[1-5]. On account of this uncertainty of response, and of possible threshold differences from unit to unit, the number of units active increases with intensity until all are excited. As this recruitment progresses, the unstimulated gaps between active units become smaller and eventually disappear. The retinal mosaic formed by the large units thus becomes functionally finer, up to a point, and visual acuity increases with intensity. Experiments on the visibility of black disks presented 20° from the fovea in the middle of a large field exposed in flashes gave results in agreement with this theory[24]. At a level about ten times the absolute threshold all the large units are active, the first branch of the acuity-intensity curve ending as a small plateau at an acuity value of 1/120. Then a break occurs and the curve rises again. Special measurement in the transition region showed that the break is genuine. By using blue light instead of white, it was also shown that the second branch is not due to cone vision coming into play but, like the first, to rod vision, for the relative position of the two branches is unaffected by the change of spectral composition of the light.

At higher intensities a similar recruiting must occur among the smaller functional units. Thus, as intensity increases from the absolute threshold to an intensity about 10^5 times higher, there is first a recruitment of large retinal units, very sensitive in terms of retinal illumination, but forming a very coarse mosaic giving only rudimentary form vision. Then this mosaic is progressively superseded by finer mosaics made up of smaller functional units, the *absolute* threshold of the various units being reached successively as the retinal illumination increases. At a certain level, cones may co-operate with rods in retinal units, particularly in the parafovea[18]. In the fovea, according to Polyak[19], cones are similarly arranged in units of different sizes, the ultimate units consisting of single cones.

The curve of Fig. 1 shows only the two main branches corresponding to rod and cone vision. Inside each branch, there is no break such as has been observed in the above experiments when fixation was used. This is most probably due to the fact that the retinal region changed progressively, the subject using the best part of his retina at each intensity.

Conclusion

Thus the absolute threshold of the smallest and least sensitive light detectors of the retina, namely the single-cone units, is probably reached only at intensities 10^5 or 10^6 times the absolute threshold for large fields—at somewhat lower intensities they generally absorb no light at all. It is in the range below this intensity-level that the major variation in such visual functions as acuity and intensity discrimination takes place. At any level within this range, the retinal units giving the best acuity performance must work in an all-or-none fashion, and the progressive recruitment of units explains the increase of acuity with intensity. It will be noted that, under such threshold conditions, nervous interaction between units (leading, for example, to phenomena of contrast) can play but little part.

The present theory takes up theories and suggestions from Hecht[29,30], von Buddenbrock[31] and Lythgoe[32]. We are indebted to many friends and colleagues for discussions and wish to thank particularly Dr. W. S. Stiles and Dr. W. A. H. Rushton. We are also grateful to Prof. A. V. Hill for his encouragement and unfailing help over many years, to Sir Frederic Bartlett, in whose laboratory experiments leading to the present theory were initiated, to Sir Henry Dale, Sir Eric Rideal, Sir Charles Lovatt Evans and Prof. E. W. H. Cruickshank, in whose laboratories they were continued, and to the Medical Research Council for its support of our investigations.

Note added in proof. Messrs. J. M. Otero and L. Plaza (*Optica Acta*, p. 8, May 1951) write : "In night vision, receptors (rods) are gathered into functional units which increase as the field brightness diminished as far as a limit value reached at the threshold. . . . The size of these functional groups controls the visual acuity for every luminous level". This seems to be the same as one of the basic ideas of our paper. Otero and Plaza give no further details, except on a form of astigmatism which they found and which they ascribe to irregularities in the shape of the rod units. Effects of the latter kind, as well as the probable overlapping of functional units, will have to be taken into consideration in a complete theory of acuity.

SEPARATE NUCLEAR AND CYTOPLASMIC ACTIONS OF DRUGS*

By PROF. J. F. DANIELLI

Department of Zoology, King's College, London, W.C.2

UNTIL quite recently pharmacology, with one exception, has proceeded without consideration of the separate actions of drugs upon the nucleus and cytoplasm of a cell. The exception is in the field of mitotic poisons, and even here we cannot yet decide whether the direct action of a mitotic drug is upon the nucleus or the cytoplasm. In a recent lecture, Mazia[1] remarked, "If the nucleus is a decisive organ of the cell, and yet physiological research has successfully ignored it, we can conclude either that physiology has been extremely lucky or obtuse . . . or that the nucleus in fact participates in physiological processes in a dimension which has been systematically neglected". Both respect for physiologists and an examination of experimental data lend strong support to the second of Mazia's alternatives. But in elucidating the actions of drugs on the nucleus and on the cytoplasm, caution obliges us to suspend judgment upon the degree to which the nucleus is a decisive organ of cells under conditions of interest to pharmacologists.

Two obvious methods of obtaining evidence of the function of the nucleus are (*a*) to remove the nuclei from cells, and (*b*) to damage nuclei, and then study the subsequent behaviour of the cells.

By enucleation of cells[1] it has been shown that the following phenomena will continue for hours, and sometimes for days, after enucleation of a cell: beating of cilia and flagella; pseudopod formation; bio-electric potentials; conduction of nerve impulse and associated recovery processes; myoneme contraction; tropistic responses; response to touch; capacity of egg cells to be fertilized; food capture; digestion of glycogen, fat and nucleic acid; contractile vacuole action; maintenance of selective permeability; mating reactions of protozoa; respiration; synthesis of phosphate esters and proteins; division of asters; cell division; the ability to exercise a morphogenetic effect; photosynthesis; plastid formation; cell extension; protoplasmic streaming. This formidable list shows that most of the 'daily life' activities of a cell can be carried on to a considerable degree without the immediate participation of the nucleus. But the ability to carry out these tasks is often reduced by enucleation, and may be lost after a few hours or days. In almost all cases enucleation results in cell death after a maximum of fifteen days: the mammalian red blood cells are exceptional in having a physiologically normal life of a hundred days or more after the loss of the nucleus.

Cells in which the nucleus has been irreversibly damaged by X-rays, ultra-violet irradiation or a nitrogen mustard show less abnormality than enucleated cells; for example, growth and division may occur normally, and life may be extended to forty days or more.

In general, failure due to enucleation first becomes evident in the more complex activities of cells. For example, differentiation is almost completely prevented; enucleated cells do not have the ability to organize themselves into a tissue; cell division is irregular; and the patterns of pseudopod formation and the degree of apparently purposive behaviour of amœbæ are affected within 5–10 min. by enucleation. It might be tempting to suppose that the changes in these complex activities are caused by the lack of the specific nuclear genes. This, however, can readily be shown to be untrue by studying the effect of transplantation of nuclei between amœbæ of different species[2].

When an enucleated amœba is renucleated with a nucleus of the same species, it recovers completely in a few minutes and will usually go on to divide and form a mass culture. When the renucleation is with a nucleus of another species, recovery is just as successful and may be followed by a few divisions, but in most cases after a few divisions death occurs[2]. However, during the period of recovery, the behaviour of the amœba is characteristic of the cytoplasm, and not of the nucleus. Thus while the nucleus is contributing one or more factors essential for short-term behaviour, these are not species-specific. On the other hand, the nucleus also contributes factors essential for long-term behaviour, and these are species-specific.

A third set of data which are of interest are the delays which occur between the application of a drug and the emergence of its action. These delays may vary between the widest limits. For example, the delay in action of acetylcholine at a neuromuscular junction may be measured in terms of milliseconds, of lewisite in causing vesication in minutes, and of mustard gas in causing vesication in hours. Agranulocytosis caused by sulphonamides may appear after a delay measurable in weeks; a tumour caused by benzpyrene after months or years; mutations caused by mustard gas only after one or more generations. Can all the instances of long delays be attributed to actions upon nuclei? To answer this question we must consider the factors involved in cellular inheritance[3]. The factors to be considered are chromosome genes, controlling characters which obey the Mendelian laws; plasmagenes, that is, genes not attached to chromosomes and so not obeying the Mendelian laws; and various intracellular parasites and symbionts of exogenous origin, including viruses which, in borderline cases, are in behaviour indistinguishable from plasmagenes. While it is widely recognized that mutations or deletions of chromosome genes may not be detectable until one or more generations later, it is not so generally realized that similar delays may occur when plasmagene changes are involved[3,4]. This is, however, the case, and consequently, while the existence of a prolonged delay before the action of a drug becomes apparent is a very good indication that its action is upon the factors involved in cellular inheritance, such delays do not permit a distinction to be made between nuclear and cytoplasmic action.

---

* Based on a public lecture given in the Department of Pharmacology, University College, London, on February 29.

A fourth set of data to be examined are the degrees of reversibility of reactions to drugs. Many drugs which act as prosthetic groups, coenzymes or inhibitors, etc., of enzymes have a readily reversible action, if used in sub-lethal doses. But other drugs may have both reversible and irreversible actions in sub-lethal doses. Thus the œstrogens have a number of readily reversible physiological actions upon mammals, but can also act as morphogenetic evocators and as carcinogens, in which instances the action is irreversible[5]. Genes also have two, apparently different, types of function. The first is to exercise a control upon one or more cellular functions; the second is to reproduce itself. Can these two types of function, in some cases, be those affected respectively by the reversible and irreversible actions of a drug? At present we have so little information about the actual mode of action of genes that only theoretical possibilities can be considered. The most important point in this connexion is that reproduction of a gene must be a phenomenon of a remarkably high degree of specificity. Consequently, a gene is unlikely to be able to reproduce while it is combined with a drug. It is thus theoretically possible that, if a gene is combined with a certain drug (or hormone) for only part of the time, the action of the drug will be reversible, whereas if the combination persists for a longer time, the gene will not reproduce, except perhaps in a modified form. In the former case we are dealing with a reversible physiological effect, and in the latter case with a gene mutation or deletion. In the field of morphogenesis the two phenomena are covered by Weiss's use of the terms 'modulation' and 'differentiation'[6].

But if we consider the possibility that drugs act upon cells in a manner parallel to that by which exogenous substrates induce the formation of adaptive enzymes, we encounter a fresh and almost totally different explanation of varying degrees of reversibility. In the absence of its substrate the amount of an enzyme to be found in a cell may be negligible; yet after introduction of the substrate the enzyme may be formed in high concentration. In a similar manner, the introduction of a drug may induce the adaptive formation of a new protein, or enzyme. Formation of the new protein may be readily reversed on withdrawing the drug. In such cases the phenomenon would be classed as a reversible physiological action, or modulation. But there are experimental data which lead us to the belief that in some cases, if once formed, a new protein may be able to reproduce itself, in which case the action may be reversed with difficulty. There is an interesting parallel to this in the phenomena of antigen formation by paramecia, studied by Sonneborn and his colleagues. In a given strain, a group of antigens may be present as alternatives. Any one antigen if present excludes formation of others of the same group. The formation of such an antigen cannot readily be prevented by chemical or physical action. But treatment with the appropriate antibody will result in the replacement of the antigen by another member of the same group. We must thus admit that, although the majority of responses of type similar to the formation of adaptive enzymes may be readily reversible, others may be reversible with difficulty, or not at all.

Thus two different modes of approach permit possible explanations of both reversible and irreversible actions of drugs. In both modes the explanations of reversible and irreversible actions involve the intervention of genes, and so involve time-lags. Now consider briefly some cases of irreversible drug action of particular interest.

1. *Mutations of chromosome genes produced by drug action.* These were first demonstrated by Auerbach and Robson[7], and by Hadorn[8]. Some of the most potent substances, such as mustard gas, are lipoid-soluble and rather inert, but slowly give rise to highly reactive and violent reagents, such as carbonium ions. The effectiveness of these substances depends upon their lipoid-solubility, which permits ready penetration; upon their inertness, which prevents them from reacting exclusively with the peripheral cytoplasm, and upon the eventual formation of a vigorous reactant. But many other effective mutagens, although having the first two properties, do not appear to have any exceptional capacity for giving rise to violent reagents. The number of such compounds known is increasing so rapidly that we must consider the possibility that the majority of chemical substances, in appropriate circumstances, are mutagenic. This in turn leads us to a new possible explanation of mutations in Nature. Hitherto radiations have been thought of as the most probable sources of mutations in Nature. Living cells have a very large number of enzymes, which if applied in sequence are capable of producing a very great variety of substances. Normally, by a process of organization not yet understood, the sequences which are permissible are limited to a relatively small number, so that a relatively small number of substances are produced in comparatively large amounts, and the majority of possible products are produced in apparently negligible traces. But these traces may still suffice for the production of mutations.

2. *Elimination of kappa from Paramecium.* Sonneborn has shown that the plasmagene-like agent kappa, which infects some paramecia, may be eliminated by the action of drugs. Normally kappa is formed in the cells at a rate which keeps pace with cellular reproduction. The action of the drugs appears to be to impede the rate of formation of kappa relative to cellular reproduction, so that eventually kappa-free cells are produced. Streptomycin has a similar action in eliminating chloroplasts from plant cells. In both cases a decrease in the rate of formation of a cyto-

plasmic factor results in its ultimate elimination, which in turn causes an irreversible change in physiological behaviour.

3. *Carcinogenesis by butter yellow in rats.* Liver tumours may be produced in rats in a few months by administration of butter yellow. If a large part of the liver of an animal is removed, the remainder grows by mitosis, etc., to about the size of the original liver. This sequence of hepatectomy and regeneration accelerates tumour production in animals treated with butter yellow. The mechanisms involved are unknown. It seems possible that plasmagene mutations are involved, and that hepatectomy, by raising the relative rate of cellular reproduction, decreases the times required for expression of the mutations. This presents some affinities to the elimination of kappa and chloroplasts.

4. *Carcinogenesis by benzpyrene.* Berenblum[9] has shown that croton oil has a remarkable effect in accelerating the appearance of skin tumours resulting from benzpyrene. If benzpyrene only is applied to the skin, tumours appear after many months. If croton oil is applied before the benzpyrene, appearance of tumours is not accelerated. But if croton oil is applied any time after the benzpyrene application, tumours appear about six weeks after the croton oil application. The type of explanation which could be involved here is that the system involves a chromosome gene producing a plasmagene necessary for normal epithelium. Deletion of the chromosome gene by benzpyrene need produce no marked effect so long as plasmagene reproduction continues. But if the plasmagene also is eliminated (for example, by croton oil), then an abnormality will appear quickly. Application of the reagents in the reverse order will not have the same effect, since if the plasmagene is first eliminated by croton oil it can be restored by the uninfluenced chromosome gene.

5. *Development of resistance by trypanosomes to arsenoxides.* Trypanosomes may become resistant to one arsenoxide and not to another. The common explanation of this is that the trypanosomes become impermeable to the type of arsenoxide concerned. But one can readily calculate that, if the trypanosome cell membrane is like that of other cells, the arsenoxides used in therapy will all penetrate rather rapidly. Consequently the explanation based on changes of permeability implies that the resistant strains have membranes different from those of any other known cell and, worse than that, that for every type of arsenoxide resistance there is a new type of membrane which is not only unlike that of any known cell but also unlike that of any other resistant strain. A much more probable explanation is that resistance is based on the development of secretory units which can pump out some types of arsenoxide and not others. Such units, by analogy with Lwoff's[10] work on kinetosomes, may be regarded as plasmagenes, perhaps controlled by chromosome genes, but self-reproducing when present, in a manner not dissimilar to surface antigens of paramecia.

However, although the various sets of data mentioned are very stimulating, when they are considered critically only the techniques of sexual crossing and nuclear transfer appear at present to give thoroughly satisfying results. The new technique of nuclear transfer has at present had only a very limited application, but has already yielded valuable results. M. J. Ord has shown that one of the nitrogen mustards, when used in concentrations sufficient to cause cell death, is not highly selective for either nucleus or cytoplasm but attacks both independently. If a nucleus is sufficiently damaged by the nitrogen mustard to die, the nucleus cannot be saved by transfer to untreated cytoplasm; nor can the cytoplasm be saved by transferring to it an untreated nucleus. The nuclear damage appears to be of two types, one involving death in a few days, the other after many days of normal behaviour. On the other hand, in collaboration with Lamaton and Harriss of the Royal Cancer Hospital, it has been shown that X-rays are highly selective for the nucleus; this result confirms calculations based on purely physical studies. We must anticipate a wealth of new information from the continued application of this technique.

CENTENARY OF THE PATENT OFFICE

By Sir JOHN BLAKE

Comptroller-General

THE "Great Seal Patent Office", formed at the end of 1852 as the single office for granting letters patent for new inventions, was the origin of the present Patent Office in London. It is true that letters patent for inventions had been granted in Great Britain for a long time previously. In fact, in the Patent Rolls of Henry VI for the year 1449, we find a grant to John Utynam for a process for making stained glass windows. The process was intended for the windows of Eton College; but it is doubtful whether it was so used. Grants of patents for inventions, at first rare, later became frequent, but the tendency was to grant monopolies even in cases where no new industry or invention had been created. This abuse was checked by the Statute of Monopolies of 1623, which limited valid grants to new inventions.

It is also true that a Patent Office had existed off Chancery Lane near the site of the present Office for a long period before 1852. The Office is referred to more than once in Pepys's "Diary": for example, under March 12, 1669, we find, "And so away to the Patent Office in Chancery Lane . . . and to the Crowne Office where we met with several good things that I most wanted and did take short notes of the dockets, and so back to the Patent Office and did the like there, and by candle-light ended". That Office was, however, concerned with only a small part of the procedure for the issue of letters patent of all kinds, a few for inventions but many for other purposes. It had no special connexion with the modern Office. Pepys describes elsewhere how he was "forced to run all up and down Chancery Lane" before receiving his letters patent of appointment as Clerk of the Acts of the Navy Office.

Before 1852, the unhappy inventor had to visit many different offices, some of them more than once and paying fees all the time, a cumbrous system satirized by Charles Dickens in his "Poor Man's Tale of a Patent". The passage of the Patent Law Amendment Act in 1852 ended this system after twenty years of agitation by inventors, scientists, engineers, industrialists and others. The reform was facilitated by the special legislation passed to enable inventors to exhibit their inventions at the Great Exhibition of 1851 without invalidating patents which might afterwards be granted to them.

The Act of 1852 placed the grant of patents in the hands of commissioners, consisting of the Lord Chancellor, the Master of the Rolls and the Law Officers of the Crown, and they set up the Office on its present site at 25 Southampton Buildings, off Chancery Lane. The Law Officers continued to hear cases where oppositions were lodged to the grant of patents and to report to the Lord Chancellor upon the advisability of granting patents; but the general control of the Office was in the hands of the Master of the Rolls. The commissioners were given power to print specifications, indexes and other publications, to present copies of these to public institutions and to set up a Register of Patents. The law relating to patents remained much the same; but the procedure for granting them was simplified and improved. Among the notable changes introduced was the obligation to file with the application a provisional or complete specification describing the invention. The provisional specification had to describe only the nature of the invention and was the direct outcome of the practice set up for the Great Exhibition. The complete specification had to describe "particularly" and "ascertain the nature of the invention and the manner in which the same is to be performed", and was the outcome of a practice which had started early in the eighteenth century requiring such a description to be filed within six months after a patent was granted as a condition of the validity of the patent. The names and purposes of these specifications have continued until the present day. The use of provisional specifications is now a valuable and special characteristic of many of the patent systems of the British Commonwealth.

One of the first tasks of the new Patent Office was to make information about patents available to the public. The specifications had formerly been enrolled in one or other of three offices, and although they could be inspected, many could only be found with considerable difficulty, if at all. Now these were printed and published with the utmost speed and distributed widely to public libraries and institutions. All the old patents prior to 1852, some thirteen thousand in number, were so printed. Classified lists of patents were prepared and a beginning was made with the preparation of a detailed scientific classification of the subject-matters contained in patents. Volumes of classified abridgments of patented inventions soon followed, and a library and a museum were established. The museum was soon transferred to South Kensington, but the library has developed into the fine scientific and technical reference library which is now open all day at the Patent Office for use by the public as well as by the staff of the Office.

The difficulty experienced by the commissioners in giving much time and attention to the affairs of the Patent Office led in 1883 to the setting up of a more business-like organization under the control of the Board of Trade. A comptroller-general was appointed and was given responsibility for trade marks and registered designs as well as for patents. It was much later that he took over responsibility for literary and artistic copyright; but here we are dealing only with his functions in connexion with patents. He was given judicial powers to decide oppositions to grants and applications for revocation of patents and other issues, the Law Officers retaining a connexion with the Office as advisers to the comptroller on legal matters and as the tribunal to hear appeals from his decisions.

Under the new organization, the initial fees for taking out patents were greatly reduced, with the result that the number of patents granted annually, which had risen from about 500 to about 2,000 on the passage of the 1852 Act and to about 4,000 by 1883, increased quickly in the next few years to as many as 10,000. In spite of the reduction in fees, more work was done in granting each patent. The examination of the specifications by a scientific staff was commenced, to ensure that the descriptions were clear and adequate and that only one invention was included in one specification. The staff gave much attention to schemes for classifying and indexing inventions, but no search was as yet made to determine the novelty of the inventions for which patents were granted. The view was expressed that the Office need not exercise paternal care for the inventor by making his search for him, but should give him every facility for making the search himself. The system allowed the inventor to get a patent relatively easily but led to the grant of many worthless patents, or patents with vague claims, which were a trap for the inventor and a nuisance to the public.

A basic change in the work of the Office was made in 1905. From then on, although the Office continued to help the inventor to help himself, it also undertook to make the search for the novelty of inventions the subject of applications for patents. The search was at first confined to British patent specifications and has been gradually extended to cover other publications, but the work of the Office in this and other respects has been gravely hampered by the two World Wars. During the Second, the Office was severely damaged by enemy bombs, and it was only due to the devotion of the staff that essential records were preserved and the building saved from complete destruction.

In recent years, the judicial duties of the comptroller have been extended and appeals from his decision have been heard by one of the judges of the High Court instead of by the Law Officers. The most recent steps in the process of enlarging his duties to protect the public and reduce the number of invalid patents granted were taken so recently as 1949, following a departmental committee of inquiry under the chairmanship of Sir Kenneth Swan. Patents for inventions which, as claimed, are lacking in novelty are now refused and notice is given to the public of all overlapping grants. In addition, the subject-matter or merits of an invention may now be considered during opposition proceedings, and the patent refused if the invention is clearly obvious to those skilled in the art.

The Office now has power to deal with most issues in connexion with the grant, amendment and revocation of patents and with other matters, such as compulsory licensing when a patented invention is not being worked to the fullest practicable extent, and disputes between employers and their employees about ownership of inventions. Although these are unusual duties for Civil servants, the topics involved are frequently highly technical and have been found to be such as can be handled reasonably and economically in the Patent Office.

The immediate problems for the Office are to dispose of the arrears of work resulting from the Second World War and its aftermath, and to make more effective the search for novelty over as wide a field as possible. At the moment, the Office is in serious need of scientific and engineering graduates to deal with the technical side of its work. Most scientists naturally look to research for their careers, but the application of research is also of vital importance; and in that connexion, the Office offers useful and interesting work for university graduates with the appropriate training and aptitude.

OBITUARIES

Prof. E. G. Conklin

By the death of Edward Grant Conklin we have lost the last representative of the great American school of classical experimental embryology which dominated this science in the period from 1900 until the rise of the Spemann school in the 1920's. Conklin retired in 1933 from the professorship of zoology at Princeton, which he had held for twenty-five years; but the fact that he had become emeritus was very far from bringing the fruitful period of his life to an end.

Conklin's main scientific work is enshrined in a series of large and fundamental papers dealing with three groups: Ascidians, *Amphioxus* and Molluscs (*Crepidula*). His work on the mollusc *Crepidula* began in 1890 but was not published until 1897. It was immediately recognized as a classical study on cell lineage. Other contemporaries of Conklin had, however, studied molluscan eggs, and his main fame rests on his description and experimental investigations on Ascidians, particularly *Styela* and *Amphioxus*. His careful descriptions of the cleavage and later development in these two groups is the foundation on which not only his own but also a very large quantity of later work by others has been based; but it was his experimental work which placed him in the front rank. In the early 1900's he found in Ascidians evidence, the clarity of which has not been surpassed to this day, for the existence of several different kinds of cytoplasm within the newly fertilized egg. Further, he demonstrated by experiment that the 'ooplasms', as they are now called, exert a determining influence over the course of the later development, so that any region composed of a particular ooplasm will always develop into the corresponding organ or tissue. He spoke of the special types of cytoplasm as 'organ-forming substances', and although our outlook on them has somewhat changed in the past forty years, the facts he produced have stood the test of time, and they, together with his discussion of them, remain as one of the three main bases of the existing theories of experimental embryology.

Although he published more than two hundred scientific papers, it would give the wrong impression to speak of Conklin as a prolific writer; his work is outstanding for that quality of clarity and precision which comes only through the long processes of checking and counter-checking the observations and maturing the thought. In spite of the time he devoted to this, he played a very full part in the general scientific life of his time, acting for long periods as editor or co-editor of the *Journal of Morphology*, the *Journal of Experimental Zoology*, the *Biological Bulletin* and *Genetics*.

Conklin's interests were not confined to the narrowly professional aspects of zoology. By birth the son of a country doctor in the Middle West, he originally intended to enter the Methodist ministry, and spent his undergraduate years at the Ohio Wesleyan University, graduating both in science, in 1885, and in arts in the following year. Even after he took the decision to devote his main energies to science, he never relinquished a profound interest in wider matters of philosophy and of man's spiritual life. During the course of his long life he published several books on such subjects, of which the best known are "The Direction of Human Evolution" (1921) and "Man, Real and Ideal: Observations and Reflections on Man's Nature, Development and Destiny" (1943). He thus earned the distinction of becoming the president both of the American Philosophical Society and the American Academy of Arts and Sciences, as well as of several purely scientific organizations such as the American Association for the Advancement of Science, the American Society of Zoologists and the American Society of Naturalists.

C. H. WADDINGTON

Prof. J. G. Lawn

JAMES GUNSON LAWN, whose eminence as a mining engineer had received world-wide recognition, died at Eshowe, Natal, on October 21 in his eighty-fourth year. Of Cornish descent and the son of a mining engineer, he was born at Dalton-in-Furness on January 4, 1868.

Before entering the Royal School of Mines in 1888 he had already acquired practical experience in the hæmatite mines in Cumberland, and this experience enabled him to smooth some of the difficulties of his fellow-students, by whom he was remembered for the readiness with which, as a somewhat senior student, he was always ready to help them.

On completing the course in 1891 and with the award of the Murchison Prize and the De la Beche Medal, Lawn returned to Cumberland as chief surveyor to the Barrow Hæmatite Steel Co. and as a lecturer in mining for the Cumberland County Council. During 1893–96 he was back at the Royal School of Mines as the instructor in mine surveying and assistant to Sir Clement Le Foster. Then began his first association with mining education and practice in South Africa. When the first South African School of Mines was set up at Kimberley in 1896 Lawn became its first principal and, in the years that followed, the organization of that School owed much to his energy and foresight. During 1903–6 his long association with the Johannesburg Consolidated Investment Co. as a consulting engineer began, although there were interludes between 1907 and 1910 when he became, in succession, head of the Camborne School of Mines (Cornwall) and the first principal and professor of mining, at Johannesburg, of the South African School of Mines and Technology, to which the Kimberley School had now been transferred.

Thus, both in the last decade of the nineteenth century and in the first of this century, Lawn's activities had been divided between mining education and the gold mining industry. It was to the latter, however, that the greater part of his life was to be devoted. For the next forty years—1910–50—(except for a period during the First World War, when he occupied posts with the Explosives Department of the Ministry of Munitions, finally as controller of that Department) his professional work was entirely linked with the manifold activities of the Johannesburg Consolidated Investment Co., first as consulting engineer, then as managing director in Johannesburg, and later as director and consulting engineer in England.

Lawn possessed wide technical knowledge and experience and, above all, was one of the wisest of the long line of mining engineers whose reputations have been made on the goldfields of South Africa.

During his long association with the Institution of Mining and Metallurgy, of which he was elected president for 1930–31, he took a very active part in discussions on technical and scientific matters. His comments were clear, concise and always constructive, even when critical. The award of the Institution's Gold Medal in 1935 and his subsequent election as an honorary member were fitting tributes to his long and unremitting services to mining education and to the mining industry.

In 1934 the University of the Witwatersrand conferred on him the honorary doctorate of science and in 1943 he was elected to the honorary fellowship of the Imperial College of Science and Technology, thus forging another link with the Royal School of Mines which he had entered as a student fifty-five years before.

In later years Prof. Lawn had found an absorbing hobby in botanical pursuits. I well remember a chance meeting with Prof. Lawn in a hotel on the Great North Road, after returning from a successful plant-hunting expedition on the slopes of Ingleborough; he was most enthusiastic about some of his finds. His last letters from South Africa were also full of details regarding interesting plants he had recently discovered near his South African home

J. A. S. Ritson

We regret to announce the following deaths:

Sir William Dampier, F.R.S., senior Fellow of Trinity College, Cambridge, on December 11, aged eighty-four.

Dr. Sven Hedin, Hon. K.C.I.E., known for his explorations of Central Asia, aged eighty-seven.

Dr. C. H. Kellaway, F.R.S., director-in-chief of the Wellcome Research Institution, London, on December 13, aged sixty-three.

NEWS and VIEWS

Long Range Weapons Establishment, Australia: Dr. C. F. Bareford

Dr. C. F. Bareford has been appointed to the post of chief superintendent of the Long Range Weapons Establishment, Australian Department of Supply, in succession to Mr. H. C. Pritchard, who returns to the United Kingdom next year. In his new office, Dr. Bareford will be responsible for the operation of both the base research and development establishment at Salisbury, and the ranges at Woomera, where trials are carried out for the Australian Government and also the Guided Weapons Directorate of the U.K. Ministry of Supply.

Dr. Bareford is a graduate of the University of Sheffield, where he carried out research under Prof. S. R. Milner on the vacuum arc and spark discharges. He gained some industrial experience with the Mazda Valve Organization during 1934–36, before joining the experimental staff of H.M. Signal School, Portsmouth. He was one of the small band of early workers on naval radar. As early as 1937, together with the late Mr. E. M. Gollin, he built a 20-cm. radar equipment, and a little later the first experimental prototype of the 50-cm. gunnery radar. In 1940, when the need for radar navigational aids became more pressing, he transferred his attention to this field, and to the associated field of precision direction-finding equipment. An early form of pulsed navigational aid was conceived and developed by a team under his leadership in the New Cavendish Laboratory in Cambridge. Special direction-finding equipments using radiation from 100 Mc./s. (33 cm.) to 10,000 Mc./s. (3·3 mm.) were evolved by this team, and were used extensively in the months prior to the Normandy landings by the Allies in 1944. Dr. Bareford had, meanwhile, assumed the control of the Radio Reception Division of the Admiralty Signal Establishment in Haslemere, and sponsored the development of the communication receiver series which is now standard equipment in H.M. ships. In 1947 Dr. Bareford became head of the Mullard Research Laboratory. Under his leadership the staff of the laboratory has grown from less than twenty to more than a hundred scientists, in addition to the ancillary staff, and has completed many important projects in the broad field of electronic engineering. In particular, the 15-MeV. linear electron accelerator and neutron spectrometer now in use at Harwell were built there. A radar system for the automatic exploration of the meteorological conditions in the upper atmosphere has been developed. The laboratory has also studied extensively cavitation phenomena, and developed instrumentation for various measurement problems and techniques for the mass production of precision components.

Melchett Medal for 1953: Dr. H. Hartley, C.B.E.

The Institute of Fuel has awarded the Melchett Medal for 1953 to Dr. Harold Hartley, in recognition of his high scientific attainments in the development of domestic heating appliances, coupled with the administrative skill with which he has guided a great industrial organization devoted to the practical efficient use of fuel. Dr. Hartley is chairman of Radiation, Ltd., manufacturers of heating and cooking appliances for domestic, commercial and industrial purposes. A native of the Isle of Man, he was educated there, at the Manchester Grammar School and at the University of Manchester, graduating in chemistry in 1907. He was then elected to a Gartside scholarship of industry and commerce, and, after a year spent in the School of Economics at Manchester, he visited Norway and Canada to study the production of power for electrochemical industries. Returning to England, he worked for three years as a Gas Research Fellow at the University of Leeds under the late Prof. W. A. Bone. In 1912 Dr. Hartley was appointed chief chemist to the Richmonds Gas Stove and Meter Co., where he built up a technical and research section and continued the work on the measurement of the radiant efficiency of gas fires which had been started at Leeds in 1908. In 1919 he was appointed head of the research department of Radiation, Ltd., on the formation of that company. At the new central research laboratories in Grosvenor Place, London, he directed many important investigations into the design of gas-fired appliances, including those culminating in the production of the Bennett/Hartley integrating radiometer for determining the radiant efficiency of domestic heating appliances. He was awarded the C.B.E. in 1952.

Official Seed Testing Station for England and Wales

MR. P. S. WELLINGTON has been appointed chief officer of the Official Seed Testing Station for England and Wales in succession to Mr. C. C. Brett, who retired in April. Born in 1919, Mr. Wellington entered the Imperial College of Science and Technology, London, in 1937. During 1939–46 he served in the Air Branch of the Royal Navy and was awarded the D.S.C. On returning to the University of London after the War, he obtained a first-class honours degree in botany. He was appointed to the Official Seed Testing Station as senior assistant to the chief officer in 1947, and has been investigating the premature sprouting in the grain of wheat. The Official Seed Testing Station is administered, on behalf of the Ministry of Agriculture and Fisheries, by the National Institute of Agricultural Botany, Cambridge.

The Imperial Institute

IN the House of Lords on December 9, Viscount Falmouth, directing attention to the report of the Tweedsmuir Committee on the Imperial Institute, asked whether the Government would consider the transfer of the Institute to a more suitable place and thus free the present site for expansion of the Imperial College of Science and Technology in order to provide additional facilities for the higher training of scientists and engineers. Viscount Falmouth was specially concerned with the expansion of the Imperial College; but, while there was general agreement in the subsequent debate as to the desirability of expanding the Imperial College, other speakers were not prepared to support its claims against the Imperial Institute, and Lord Hailey asked for a specific assurance from the Government that it did not contemplate the abandonment of the present Institute building in favour of the College. Earl De La Warr, replying for the Government, declined to make any definite statement regarding the Government's future schemes for higher technological education or the Government's views on the Tweedsmuir Report. A definite statement of the Government's policy with regard to higher technological education, it was said, would be made early in the New Year. As regards the Imperial Institute, since the Institute is financed and supported by forty-nine governments in all, transfer of the Institute to another site could only occur, if at all, after discussion with the Institute and all those Dominion and Colonial governments which are partners in its maintenance. He added that, as soon as it is possible to discuss definite proposals, the Government, which already controls so much of the land adjoining the College buildings at South Kensington, will be concerned to assist the development of the Imperial College in the best way that it can; but he could not say in advance how far that may involve the Imperial Institute.

Journal of the Royal Society of Arts: 1852–1952

THE first issue of the *Journal of the Royal Society of Arts* was published on Friday, November 26, 1852, and to mark this event the centenary number of the *Journal* (101, No. 4887; 1952) briefly records its history. The Royal Society of Arts is, of course, nearly twice as old as its *Journal*, having been founded in 1754, and its activities were at first chronicled in various publications and in its annual *Transactions*. Dr. James Booth, F.R.S., vicar of Wandsworth, who was an ordinary member of the Society, first suggested the idea of a weekly journal in a letter addressed to the Council of the Society in 1852. In this letter he set out in considerable detail the scheme for a weekly newspaper, which should record all the Society's proceedings, serve as a medium between the Society and allied institutions and form a permanent record of the progress of science, art and industry. This project was taken up, and weekly publication was continued until March 22, 1940, since when the *Journal* has appeared at fortnightly intervals, still published, as was the first issue, on a Friday. The circulation almost automatically follows the membership of the Society: in 1853 it was 2,250, and this more or less consistently increased until 1873, when it was 4,350; during 1873–1932 it dropped to 3,000–3,500, but since then it has regularly increased to its present figure of about 6,000 members. The chief aim of the *Journal* has remained constant—namely, the publication of the great mass of information contained in the authoritative papers read to the Society and the often most interesting and sometimes entertaining discussions which they have provoked. There has been virtually no limit to the range of subject-matter, provided only that there is, in each individual exposition, some germ of progress, some new line of approach that tends to the advancement of human welfare. To the published papers there have been added reports of the Society's activities; illustrations in the shape of photographs, drawings, maps and diagrams; book reviews; obituaries; miscellaneous notes of interest; and announcements of meetings of other societies. For a centenarian, the *Journal of the Royal Society of Arts* is an active old gentleman; may the second hundred years of its existence be as flourishing as the first.

University of Paris: Honorary Degrees

AT a Séance solennelle de Rentrée in the amphitheatre of the Sorbonne held on November 29, and in the presence of the President of the French Republic and the Minister of National Education M. le Recteur Sarrailh conferred the degree of doctor *honoris causa* of the University of Paris on the following: Dr. O. da Fonseca, director of the Instituto Oswaldo Cruz of Rio de Janeiro; Prof. R. F. Loeb, professor of medicine in Columbia University; Prof. M. Siegbahn, professor in the Royal Academy of Sciences of Sweden; Prof. H. Weyl, honorary professor in the Institute for Advanced Study in Princeton; Sir Rudolph Peters, professor of biochemistry in the University of Oxford; and Prof. A. I. Virtanen, professor of biochemistry in the Valio Institute of Helsinki. Similar degrees were also conferred upon four other persons distinguished in law and letters.

Agricultural Education

The Minister of Agriculture and Fisheries, after consultation with the Minister of Education, has set up a 'working party' with the following terms of reference: "To review the relations between the agricultural education service of Local Authorities and the National Agricultural Advisory Service, and to make proposals for their more effective co-operation; to examine the need for an inspectorate of agricultural education; and to consider the future of the Joint Advisory Committee on Agricultural Education".

The membership of the 'working party' is as follows: Lord Carrington, Joint Parliamentary Secretary to the Ministry of Agriculture and Fisheries (*Chairman*); F. Bray, under-secretary in the Ministry of Education; E. Shaw Browne, chairman of the Nottinghamshire Agricultural Executive Committee; W. S. Gibson, provincial director, National Agricultural Advisory Service; Dr. T. Loveday, chairman of the Joint Advisory Committee on Agricultural Education; J. H. Parker Oxspring, director of education, Staffordshire; Prof. R. Alun Roberts, University College of North Wales, Bangor; F. Rollinson, recently of the National Union of Agricultural Workers; Sir James Scott-Watson, chief scientific adviser to the Ministry of Agriculture and Fisheries; W. J. Simmons, farmer; Sir Offley Wakeman, chairman of the Shropshire Education Committee; C. H. M. Wilcox, under-secretary in the Ministry of Agriculture and Fisheries. All communications should be sent to Mr. H. F. Greenfield, at the Ministry of Agriculture and Fisheries, 1–4 Cambridge Terrace, Regent's Park, London, N.W.1.

Science in Communist States

The Society for Freedom in Science has recently published Occasional Pamphlet No. 13, under the title "Science in a Satellite State of the Soviet Union" (pp. 16; from the Department of Zoology, University Museum, Oxford; 1*s.* 3*d.*), which is a summary, without comment, of speeches made at the "Ideological Conference of University Scientific Workers", held at Brno, Czechoslovakia, during February 27–March 1, 1952, the material being taken from bulletins of the Czechoslovak News Agency. No more dignified way could have been adopted of correcting the impression sometimes held that in Communist States the man of science is free to pursue the search for truth wherever it may lead him. The speeches summarized in the pamphlet show clearly the domination and direction of science by political ideologies in such countries, how secondary can be the loyalty of the scientific worker to his own discipline, and the way his thinking is required to be subservient to the doctrines and needs of the State.

Royal Society: Officers and Council

The following have been elected Officers and Council of the Royal Society for the ensuing year: *President:* Dr. E. D. Adrian; *Treasurer and Vice-President:* Sir Thomas Merton; *Secretaries and Vice-Presidents:* Sir Edward Salisbury and Sir David Brunt; *Foreign Secretary:* Sir Cyril Hinshelwood; *Other Members of Council:* Prof. P. A. Buxton, Mr. H. Constant, Prof. P. I. Dee, Prof. E. C. Dodds, Prof. H. J. Emeléus, Sir Howard Florey (*vice-president*), Prof. D. R. Hartree, Prof. E. G. T. Liddell, Prof. E. J. Maskell, Prof. R. A. McCance, Prof. H. H. Plaskett, Prof. W. J. Pugh, Prof. Alexander Robertson, Dr. R. Stoneley, Prof. G. Temple, Prof. C. M. Yonge.

Announcements

Prof. Arthur Holmes, regius professor of geology in the University of Edinburgh, has been elected a corresponding member of the Geological Society of Stockholm.

Prof. R. J. W. LeFèvre, professor of chemistry in the University of Sydney, has been awarded the H. G. Smith Memorial Medal by the Royal Australian Chemical Institute, in recognition of his contributions to physical organic chemistry over the past ten years.

Dr. T. H. C. Taylor has been appointed as from April 1953 to the recently created post of deputy director, in the senior principal scientific officer grade of the Scientific Civil Service, at the Anti-Locust Research Centre, London. Dr. Taylor is at present assistant director of the Commonwealth Institute of Entomology, which he joined in 1944, after long and distinguished service in Fiji and Uganda, mainly connected with research on the ecological and biological control of insects.

Mr. M. W. Perrin, at present research adviser to Imperial Chemical Industries, Ltd., has been appointed chairman of the Wellcome Foundation, Ltd., in succession to Mr. H. E. Sier, who is retiring at the end of January. Before the Second World War Mr. Perrin was a member of the Research Department of the Alkali Division, and also of the Headquarters Research Department of Imperial Chemical Industries, Ltd. During the War he was assistant director of Tube Alloys (the war-time atomic energy organization), and from 1946 until 1951 was deputy controller (technical policy) in the Division of Atomic Energy of the Ministry of Supply.

In order to encourage the writing of papers at a standard suitable for assimilation by a non-specialist reader having some general scientific knowledge, the publishers of the scientific journal *Research* are organizing an essay competition, with prizes of £100, £50 and possibly others as well, for which entries may be made by persons actively engaged on research work. Such essays should be about three thousand words in length and should deal with any recent scientific investigation (not necessarily the writer's own work) and its potential application to industry. Entries, which will be judged by a committee to be appointed by the Scientific Advisory Board of *Research*, should reach the offices of *Research*, 4–6 Bell Yard, London, W.C.2, on or before April 30, 1953.

The Institution of Naval Architects is offering during 1953 the following scholarships to British subjects (age limit shown in brackets), which, except where otherwise stated, must be applied for before May 30, 1953: Institution scholarship in naval architecture (23), for apprentices or pupils in the Royal dockyards or private shipyard (entries before January 15); Trewent scholarship in naval architecture (20), for apprentices or pupils in private shipyards; Denny scholarship in naval architecture and one in marine engineering (19), tenable for four years in the University of Glasgow, with apprenticeship of five years; Parsons scholarship in marine engineering (21), for apprentices or pupils in marine engine works or the Royal dockyards. Further particulars can be obtained from the secretary of the Institution at 10 Upper Belgrave Street, London, S.W.1.

UNUSUAL FOODS FOR HUMAN CONSUMPTION

IT has been estimated by M. Sorre[1] that, of the two million known species of animals, only fifty have been domesticated and normally contribute to the food supplies; and that, similarly, out of the quarter of a million known vegetable species, only about six hundred are cultivated by man. J. De Castro[2], in discussing the figures, has contrasted the limited range of foods used by the inhabitants of Europe and North America with the vast number of native plants which contribute to the diet of primitive peoples. These observations received full support at a conference organized at Bedford College, London, on October 18 by the Nutrition Society when, under the general title of "Unusual Foods for Human Consumption", a series of seven papers was presented. Dr. R. B. Hawes acted as chairman of the symposium, which attracted some two hundred members and guests.

During the morning session, consideration was given to three types of unusual foods: Dr. W. A. P. Black spoke on "Seaweeds and their Value in Foodstuffs"; Dr. J. Ramsbottom on "Mushrooms and Toadstools"; and Dr. W. S. Bristowe on "Insects as Food".

In the first paper, an account was given of the uses of seaweeds in different parts of the world, and it was evident that investigations carried out during the past decade, in Scotland and elsewhere, have made important contributions to our knowledge of the chemical composition of different species and have also provided valuable information regarding methods for the efficient harvesting and processing of marine vegetation. Dr. Black surveyed, among other matters, the production from seaweeds of substances of nutritive value which are now finding a place in food manufacture.

The report on the edible fungi directed attention to their widespread use in many countries of continental Europe where, in contrast to the position in the British Isles, the fungi are regarded not as relatively expensive luxuries but as important vegetables, eaten both in the fresh state and also, during the winter months, in preserved forms.

Insects, etc., are not normally held in high esteem in Europe; but it was clear from Dr. Bristowe's review that, in Siam, Indo-China and in certain parts of India, spiders are regarded as normal items in the diet and that in many other countries insects of different types are used as minor foods. Dr. Bristowe gave an account of his personal experiences in Asia, where he was able to follow local dietary customs.

The contrast between the European town-dweller and the inhabitants of other regions was frequently demonstrated in the afternoon sessions of the symposium, when reviews were given by Dr. H. M. Sinclair on "The Diet of Canadian Indians and Eskimos"; by Dr. G. H. Bourne on "The Food of Australian Aborigines"; by Dr. F. Aylward on "The Indigenous Foods of Mexico and Central America"; and by Dr. B. M. Nicol on "Protein in the Diet of the Isoko Tribe of the Niger Delta".

These papers all revealed the ingenuity of man in making full use of the local plants and animals, and in becoming master of his environment. Certainly, of the Australian aborigine, it may be said that, in terms of food, nothing living is alien to him—the caterpillar and the moth, the frog and the kangaroo, are trapped by appropriate but effective methods and eaten with relish. Similarly the African tribe examined by Dr. Nicol was shown to be catholic in taste; snails, frogs and crocodiles, as well as a variety of plant foods, have their place in the diet. Dr. Nicol's paper revealed the difficulty in making satisfactory dietary surveys in areas where the ordinary staple foods are supplemented, perhaps at irregular intervals, through hunting, shooting and fishing. These occasional supplements make important contributions to the diet.

A similar difficulty in making dietary surveys was experienced in Mexico and Central America where, as reported by Dr. Aylward, the inhabitants preserve dietary traditions that go back into prehistory. Examples were given of methods of food preparation which, although long in use, have only recently been shown to have a sound biochemical basis. Thus the Indian is able to use certain varieties of plants which are poisonous in a raw state, by methods which involve a preliminary grating followed by cooking, a technique which is now known to be effective in destroying toxic components such as the cyanophoric glycosides. Recent scientific investigations have also revealed the advantages of the traditional method of making the tortilla, the daily bread of the Indian; the whole maize is treated with lime, and thus the mineral content of the final product is increased and the danger of widespread dietary calcium deficiencies diminished[3].

By comparison with the inhabitants of tropical and semi-tropical regions, the Eskimos live on a much more restricted diet, especially during the long Arctic winters. Dr. Sinclair showed how the Eskimos have successfully adapted themselves to an unfavourable environment so as to obtain a diet normally adequate in calories and in both major and minor nutrients. Contrary to reports from other northern areas, the groups examined did not eat excessive amounts of fat.

The discussion of the papers ranged over many topics. Dr. H. E. Magee, for example, stressed the importance of quantitative considerations. A food constituent such as vitamin B_1 present in very small amounts in a staple food may be of great value because of the relatively large amounts of the staple eaten per day; on the other hand, a minor or occasional food is of value when it contains a high proportion of one or more accessory factors.

Mr. A. L. Bacharach, commenting on the Mexican tortilla, directed attention to the war-time controversies in Great Britain relating to the addition of calcium carbonate to National flour; it would appear that we had belatedly followed the good example of the Indian.

Other speakers, drawing on their experiences overseas, gave further examples of unusual food habits, and the symposium as a whole reflected the newer 'global approach' to nutrition; the fundamental biochemical investigations of the past half-century, carried out mainly in Europe and in North America, provide the basis for the approach to the nutrition problems on all continents, yet there is clearly much to be learnt from well-established food habits in Africa and elsewhere, in that primitive peoples in many areas have succeeded in reaching good dietary standards.

The papers given at the conference (which will be published in the *Proceedings* of the Society) may be regarded as a continuation of earlier symposia on Colonial problems[4] and on nutritional conditions in prisoner-of-war camps in Asia[5]. They should serve a useful purpose in providing information regarding the actual and potential food supplies of under-developed areas, and in this way should assist in furthering the work being carried out on these topics under the auspices of the Colonial Office and other national and international agencies.

APPLICATIONS OF COMMUNICATION THEORY

TWO years ago, during September 26–29, 1950, a symposium was held in London of a group of some hundred and twenty men of diverse scientific interests —communication engineers, mathematicians, physicists, biologists, psychologists and others—all of whom were concerned in one way or another with the concept of the communication of information (see *Nature*, 167, 20; 1950). The meeting was prompted by the recognition of the importance of recent developments in the theory of communication which revealed, and gave promise of clarifying, connexions between previously largely unrelated fields of research concerned with different aspects of the processes by which living organisms convey information. The purpose of the symposium was to afford the opportunity for a discussion of the nature of this recent work and of its potentialities in various branches of science.

It was decided that there should follow in due course a second symposium having the more limited objective of examining what of practical value had resulted from the application of this theoretical work to the problems of electrical communication, and this second meeting was held in London in the Lecture Theatre of the Institution of Electrical Engineers, during September 22–26. The participants on this occasion were mainly practising communication engineers, though other interests were well represented, and they were even more international than those who attended the earlier symposium. The two hundred and seventy present included ninety visitors from sixteen countries abroad. The chairman of the opening session was Sir Noel Ashbridge, retiring director of technical services of the British Broadcasting Corporation.

In the opening address, Prof. Willis Jackson referred to the two distinct, though closely interrelated, sides of the recent theoretical work: one, the theory of the representation of signals, that is, the analysis of signals into the basic elements—the 'alphabet'—in which it is intended to communicate; and the other, the statistical theory of communication, that is, the application of probability theory to the communication of these elements. Prof. Jackson remarked on the value of the theory in affording means for the quantitative comparison of different transmission systems (different forms of modulation and coding); on the progress being made in the development of techniques for the extraction of signals from a noisy background; and on the considerable activity which it had stimulated in studies such as the analysis and synthesis of speech, the improvement of speech recognition in noisy conditions, the possibilities of compressing the band-width required in speech and television channels, the mechanism of hearing, etc. He remarked that communication theory has perhaps achieved little as yet in the last-named fields, but that to make a reproach of this would be on about the same level as pointing out that Carnot and Kelvin did not invent the gas-turbine. A basic theory is a compass rather than a vehicle, and there is little reason to doubt that, in this case as in others, it will be supported in due course by the inventive imagination on which progress largely depends.

Prof. Jackson then directed attention, in the absence of the author, to the "Summary of Communication Theory" which Dr. D. Gabor had prepared for the benefit of the participants. In this paper Dr. Gabor discussed the parts played, in the development of the theory of communication, by classical Fourier analysis, its modification by treating time as a 'running' variable and the application of probability theory to signal data; and he detailed, in terms based mainly on the work of Dr. C. E. Shannon, the principal concepts, theorems and results concerning the two aspects of the modern work, signal analysis and the statistical theory of communication, mentioned above.

The first two days of the symposium were devoted mainly to problems concerning the detection of signals when mixed with noise, and served to emphasize that the detector must be regarded essentially as giving a probability distribution rather than a precise, error-free, extracted signal. A paper by P. H. Blundell suggested that it is not permissible to regard the whole of this (*a posteriori*) distribution, in the mean, as a rate of information, since at any instant during the communication it cannot all be used. This argument aroused considerable discussion which served to clarify some important misconceptions. Prof. Z. Jelonek followed with a summary of the results of a comparative study of various modulation systems in which he had calculated their respective theoretical rates of transmission of information. This paper, and an allied one by Prof. S. Goldman (United States), demonstrated the quantitative value of the statistical theory, and revealed the limited practicable scope which is available for improvement in the methods of modulation now in use.

New contributions to the theory and art of pulse modulation were made by F. de Jager (Netherlands), who described a one-unit code system of pulse-code modulation to which he had given the name "delta-modulation"; by C. W. Earp, who discussed a possible modified form of pulse-code modulation, which he called the "ambiguous index system"; by H. W. F. Groenewout (Netherlands), who gave the results of an investigation of distortion in pulse-code modulation systems; and by Dr. D. M. MacKay, who raised an interesting problem concerning the transmission of neural impulses.

Allied to these papers were others by R. H. Barker, who dealt with the important problem of the group synchronization of binary digital systems, and by Drs. A. E. Laemmel and D. A. Huffman (United States), who discussed the construction of codes, the former of error-correcting codes involving the deliberate inclusion of redundancy, in the form of additional code signals, for the purpose of combating noise, and the latter of codes to remove excessive redundancy, where this exists.

The discussion of the extraction of signals from noise, related more particularly to the detection of pulsed radar signals, and to the comparative efficiency in this respect of alternative methods of detection, was continued in papers by D. E. Hampton, by Dr. W. Meyer-Eppler (Germany), and by Profs. R. M. Fano and D. Middleton (United States). The two latter directed attention to calculation of the *a posteriori* probability of the received message from the *a priori* distribution and the assumed statistics of noise, and extended and generalized earlier work on the theory of ideal detectors. Middleton discussed his comparative studies based on several types of optimum test of a statistical hypothesis against an alternative —signal and noise as against noise— and his consideration of three types of 'observer', namely, the 'Neyman-Pearson', the 'ideal' (Siegert) and the 'sequential', for which he had computed the corresponding betting-curves. He also described an analogue electronic device constructed by Dr. R. A. Johnson and himself for measuring the correlation functions of modulated carriers and noise following a non-linear device. One interesting conclusion to be drawn from this series of papers is that no marked inefficiency is associated with the types of detector now in use, and that in fact we cannot hope to go much better, which further illustrates the value of the modern communication theory in enabling calculation of the limits of performance which practical systems cannot hope to exceed. There followed a series of papers by Drs. A. E. Bailey, R. L. Beurle and P. L. Waters, dealing with the question of information storage, and the comparative merits of magnetic, acoustic and electrostatic systems applied to signal integration.

On the morning of the third day the discussion moved from statistical communication theory to a series of papers by D. H. Hamsher (United States), Dr. M. Cotte (France), Prof. K. Küpfmüller (Germany) and Prof. T. Laurent (Sweden), concerned with the transient distortion and delay characteristics of transmission channels and with general signal analysis, chiefly with reference to telegraph and television systems, where the wave-shape of the signals is of prime importance. This was followed during the afternoon by consideration of the information content of pictures and of its transmission by facsimile and television. Papers by Dr. J. Loeb (France), and by Dr. E. C. Cherry and G. G. Gouriet, emphasized the excessive redundancy which exists in facsimile and television signals by virtue of the fact that the probability of a black or grey 'dot' on any real picture is far less than that of a plain surface element. Thus existing practical systems are potentially capable of transmitting patterns which are far more complex than ever arise in real pictures. Dr. Loeb pointed out that scanning is a wasteful and unnecessary procedure with simple pictures, such as sketches, charts, handwriting, etc., and described the principles of pantograph and stopping-spot devices which can trace the picture automatically and the output of which can be coded for transmission to a tracing pencil at the receiver. The second authors proposed a system of velocity modulation applied to television to accomplish the same end. The discussion of these papers centred, somewhat naturally, round the psychological problem of 'recognition'. A succeeding paper by Dr. G. Valensi (Switzerland) dealt with the coding of colour-television signals. He stressed the merits of the modern view of the problem, which regards the black-white version of the picture as one signal and the superposed colour as a second—as distinct from the simultaneous transmission of three pictures, red, blue and green—and proceeded to discuss the possible use of a sub-divided Maxwell colour triangle for defining the colour information.

Speech and hearing formed the subject-matter of the programme on September 25. One group of papers, by J. Berry, D. L. Richards and J. Swaffield, dealt with studies of conversational speech on the telephone. They described statistical measurements of the frequency of occurrence of particular words and syllables, consonants and vowels, strong and weak word-forms, etc., and also an attempt to relate the conventional methods of measuring the performance of speech-links to the concepts of 'channel capacity' and 'information rate' as defined in the modern theory of communication. Another group of papers, by Drs. G. E. Peterson, K. H. Davis, R. Biddulph and S. Balashek (United States) and by Drs. D. Fry and P. Denes, was devoted to the problem of speech recognition and to consideration of the principles whereby a 'machine' might print in standard symbols, or respond in some other recognizable way, to received human speech. These papers emphasized that a great deal of information is lost when speech is transformed to writing and that the main problem is to determine what are the minimal elements of speech which ensure identification. Dr. G. Raisbeck, who presented the paper by Drs. Davis, Biddulph and Balashek, described a machine which is able to identify each of the numerals, one to nine, though only when spoken by the same individual. The problems involved in making it capable of responding similarly to different voices, and of recognizing continuous phrases and sentences, are indeed complex and difficult ones, but carry some far-reaching implications.

These papers were followed by two demonstrations, by W. Lawrence and by Dr. W. G. Tuller (United States), of machines which performed the complementary operation, that of uttering 'spoken' words when driven by electrical stimuli of comparatively simple form. This fascinating work may provide an important 'synthesis' approach to the study of the speech recognition problem.

A particularly interesting supplementary paper describing a new approach to the theory of hearing was presented by Dr. W. H. Huggins (United States). He began by considering the measurement of the pitch of a damped wave by means of a 'phase detector' and proceeded to suggest that while the basilar membrane itself does not possess suitable elastic properties to account for the fine pitch discrimination of the human ear, the tectorial membrane, with which it is connected by hair-cells, has similar frequency-selective properties to those of the phase detector. Dr. Huggins showed that these proposals conform well with the experimental results obtained by von Békésy, Galambos and Davis in studies of the cochlea of the cat.

The topics considered on the final day lay somewhat aside the main theme of the symposium but were nevertheless much appreciated by a large audience. Two papers concerned with language and linguistics, presented by D. A. Bell and by Prof. B. Mandelbrot (France), afforded opportunity for a considerable discussion among the linguists present, and revealed how closely the theories of communication and of language are related and how beneficial progress in one can be to the other. An important succeeding paper by Dr. Y. Bar Hillel and Prof. R. Carnap (United States) referred to the mis-application by some men of science of the terminology and theorems of statistical communication theory to fields in which the term information is used, presystematically, in a semantic sense (one involving the contents or designata of symbols) or even in a pragmatic sense (one involving the users of these symbols) and to the misleading consequences which can result. They presented the outlines of a theory of semantic information based on the theory of inductive probability recently developed by Prof. Carnap, and suggested that this should serve as a better approximation than the present statistical theory for application to fields like psychology and the social sciences.

An interesting application of the results and methods of communication theory to optics was described by Prof. A. Blanc-Lapierre (France); and in a paper entitled "Generators of Information", Dr. D. M. MacKay raised a number of difficult questions, such as—Can we trace the information in a channel back to an ultimate source, or are we restricted to considering information transducers only? Communication theory generally accepts the *a priori* existence of an agreed alphabet. where does this arise?—and illustrated his arguments by descriptions of simple electrical machines.

The symposium concluded with a general discussion, in which Dr. E. C. Cherry gave a summary of the main questions which had been raised during the week, and with an expression of appreciation by Prof. Willis Jackson to the British Broadcasting Corporation and the Ministry of Supply for the financial assistance they had afforded. The proceedings of the symposium are to be published by Butterworths Scientific Publications, Ltd.

THIRD INTERNATIONAL CONGRESS ON ASTRONAUTICS

THE Third International Congress on Astronautics, held in Stuttgart during the week September 1–6, was attended by fifty official delegates and more than a hundred visitors. During the first two days the business of the International Astronautical Federation was discussed. The major item was the constitution of the Federation, which was agreed to and signed by all societies represented, these being the national societies of the Argentine, Austria, Denmark, Germany, Great Britain, Holland, Italy, Norway, Sweden and Switzerland, together with the American Rocket Society, Chicago Rocket Society, Detroit Rocket Society, Pacific Rocket Society and Reaction Research Society of the United States. The following officers were elected: ***President***, Dr. E. Sänger (Germany); ***Vice-Presidents***, Andrew G. Haley (United States) and Dr. L. R. Shepherd (Great Britain); ***Honorary Vice-President for International Relations***, Dr. G. Loeser (Germany); and ***Secretary***, J. Stemmer (Switzerland).

Of the twenty-three papers presented during the technical sessions the majority were devoted to problems of detail in space-flight. In his paper "Inter-orbital Transfer with Minimum Propellant Expenditure", D. F. Lawden (British Interplanetary Society) discussed the problem of the transfer of a rocket between two coplanar elliptic orbits, about the same centre of inverse square law attraction, along a trajectory requiring a minimum of propellant expenditure. His solution involved a number of impulsive thrusts, and equations were obtained from which the magnitude and directions of these thrusts could be calculated in particular cases. In the case of transfer between circular orbits, the solution was shown to be equivalent to that due to Hohmann[1].

In "Exposure Hazards from Cosmic Radiation at Extreme Altitudes and in Free Space", Dr. H. J. Schaefer (American Rocket Society) reviewed the present position. In recent years direct evidence has been obtained of the existence of a component of primary cosmic radiation consisting of heavy nuclei. It is known that other types of primary radiation and secondary radiation are not dangerous, but this discovery places the problem of a possible exposure hazard for human beings, in the region of the primary radiation, on a new basis. The heavy primaries are characterized by an extremely high specific ionization and by a large radial spread of the ionization dose around the particle tracks. Either of these properties might endow them with a greatly increased biological effectiveness which cannot be measured effectively in terms of ordinary biological dosage units. The screening effect of the geomagnetic field is such, however, that these particles of comparatively low energy and heavy nuclei would be almost totally excluded from reaching the earth except near the poles. It remains an open question whether such particles are present or not in large quantities in the primary cosmic-ray spectrum in free space away from a body with a shielding magnetic field. It appears that it would probably be safe for human beings to venture a few hundred miles from the earth's surface, but no definite statement can be made for more remote space. A further alternative is the possible existence of a heliomagnetic field which could screen part of the solar system. However, no clear experimental evidence of its existence is available.

Experiments to investigate the biological effects of these heavy primaries were described by Prof. J. Eugster (Schweizerische Astronautische Arbeitsgemeinschaft) in his paper "Die biologische Wirkung der Kosmischen Strahlung, Methoden und neueste Ergebnisse". Investigation of the biological effects on eggs of *Artemia salina* and human and animal living tissue was carried out by taking the specimens to heights of 28,000–30,000 m. in sounding-balloons. Direct hits by highly ionizing components on *Artemia* eggs had a lethal effect, the hatching-rate after exposure being zero. The comparative rates at the surface and at a station shielded by some 2,100 m. of rock were 96 and 9 per cent, respectively. The low hatching-rate of the eggs exposed underground was due to considerable neutron radiation which was found to be present. Evaluation of the results of exposure of human and animal tissues was not complete.

A further medical problem of great interest in astronautics was discussed by Dr. A. E. Slater (British Interplanetary Society) in his paper "Sensory Perceptions of the Weightless Condition". It has been suggested that the otolith organs of the inner ear might give confused results when not subjected to a gravitational force or acceleration, and might thus induce a feeling of 'space-sickness'—perhaps akin to sea-sickness. In the weightless condition, the impulse frequency of the maculæ might or might not fall to zero. If there is a certain basic minimum frequency which is present during the weightless condition, then the different otolith organs the maculæ of which face in different directions would give contradictory information, and a feeling of 'space-sickness' might exist. However, it has been shown by both Adrian and Lowenstein that some nerve fibres of the otolith organs do not carry impulses when the head is in certain positions. In the weightless condition, therefore, it seems improbable that any impulses would be present. Some forms of deafness are due to both middle ears being out of action. No impulses can be transmitted under these conditions, and yet no ill-effects are felt. It is therefore thought that weightlessness also would bring no ill-effects. The main function of the otolith organs is almost certainly that of adapting the body to the effects of gravity by controlling the tone of the muscles used for balancing, and causing instant adjustments of muscular tension whenever necessary.

PAN-AMERICAN INSTITUTE OF GEOGRAPHY AND HISTORY

AMONG the specialist agencies set up by the Governments of the American Republics is the Pan-American Institute of Geography and History (PAIGH). Much of the work of the Institute is carried out by the three Commissions which were set up at the fourth general assembly held at Caracas in 1946. These three Commissions deal, respectively, with cartography, geography and history.

The first meeting of the Commission on Geography or, as it has come to be called, the Pan-American Consultation on Geography, was held in Rio de Janeiro during September 1949; the second in Santiago, Chile, during October 1950; and the third in Washington, D.C., during July 25–August 4, 1952. Future plans are to hold meetings of the Commission every two years. The twenty governments which are members each send official representatives, and interested international organizations, such as Unesco, participate in an observer capacity; the Canadian Government also sends observers.

The chairman of the Consultation meeting at Washington, D.C., was Prof. Preston E. James (United States). All the proceedings were in English, Spanish or Portuguese, with simultaneous translation available for all meetings, which were held in conference rooms provided by the United States State Department. As an official gathering, attendance was limited to delegates officially appointed or special invitees.

Some indication of the wide range of subjects covered by the conference is indicated by the existence of five sections which carried on their meetings simultaneously, and which dealt, respectively, with physical geography and biogeography, human geography, regional geography, geography of the Americas, teaching and methodology.

Between Consultations the action programme of the Commission is entrusted to five permanent committees, which deal, respectively, with basic natural resources, settlement and colonization, land classification and survey of land use, geography of the Americas, and teaching and methodology.

The American republics are acutely aware of the need for a comprehensive study of their geographical resources as a prelude to schemes of land planning and conservation of resources. Not only are land-use surveys planned and in progress in many areas, but also active steps are being taken to set up a training centre or training centres where those with a basic university training can be given the necessary instruction to enable them to take their place in the survey teams which are planned. It is proposed to set up a government-sponsored college for this purpose, probably in Rio de Janeiro.

L. Dudley Stamp

REACTIVITY OF PROTEIN FIBRES

DURING the annual conference of the Society of Leather Trades' Chemists, held at the University of Leeds during September 19–20, the fifth Procter Memorial Lecture was delivered by Prof. J. B. Speakman, professor of textile industries in the University of Leeds, his subject being "The Reactivity of Protein Fibres: Some Analogies between Keratin and Collagen".

After paying tribute to Prof. Procter, and those members of the staff of the Department of Leather Industries in the University of Leeds—Mr. F. C. Thompson and Prof. W. R. Atkin—who had worked with him, Prof. Speakman began to develop his comparison of keratin and collagen in terms of the amino-acid composition. Because of the close similarity in the proportions of basic and (free) carboxylic acid side-chains, close similarity in the reactions with acids and alkalis is to be expected, apart from complications due to the presence of cystine in keratin. The titration curves of the two proteins were compared and their reaction with acids discussed in detail. Prof. Speakman suggested that differences in the acid titration curves of different forms of collagen are due to neglect of differences in swelling, and to errors in the calculated amount of combined acid when no account is taken of the difference in concentration of acid inside and outside the collagen. In terms of the Donnan theory of membrane equilibrium, methods of calculating the 'true' titration curve were outlined, the 'true' curve representing the correct amounts of acid combined at different internal *p*H values.

Prof. Speakman next turned his attention to the action of neutral salts on keratin, potassium chloride and lithium bromide being chosen as examples of two main types. It was shown that the former causes breakdown of salt linkage through the association of potassium and chlorine ions with the oppositely charged ions of the linkage. Lithium bromide has the same effect but, in addition, causes breakdown of hydrogen bond at concentrations below about 5·8 *M*. Above this concentration, co-ordination with hydrophilic groups in neighbouring chains leads to some measure of cross-linking.

Close analogy between keratin and collagen is also found in the supercontraction of the former and the hydrothermal shrinkage of the latter. Although the molecular structure of keratin is more stable than that of collagen, because of cystine linkages in the former, breakdown of hydrogen bond by means of a 50 per cent solution of phenol promotes the contraction of wool fibres at high temperatures. By determining the temperature at which 20 per cent contraction occurs in 20 minutes, in accordance with

Zahn's procedure, it was shown that the least plastic wool fibres have greater cohesion than the most plastic.

In relation to tanning, it was shown that formaldehyde, benzoquinone and basic chromium acetate cross-link keratin, and that cross-linking reactions are to be expected with collagen. The fact that the strength of collagen is reduced by tanning is probably due to the effect of cross-linking on the extensibility and surface friction of the ultimate fibres. It was suggested that frictional measurements on tanned and untanned collagen fibres would be a profitable study.

Finally, some attention was given to the proportions of crystalline and amorphous material in protein fibres. A new method of measuring the proportions with heavy water was described, and it was suggested that the polymerization of suitable monomers within the fibres, with subsequent cross-linking where possible, provides an interesting possibility of overcoming the accessibility problem and, at the same time, of developing new tanning processes.

NATIONAL RESEARCH COUNCIL OF CANADA

REPORT FOR THE YEAR 1951–52

THE thirty-fifth annual report for 1951–52 of the National Research Council of Canada* is the last to appear over the name of Dr. C. J. Mackenzie as president, for he has now become president of the new Crown company, Atomic Energy of Canada, Ltd., an organization to which the responsibility of operating the Chalk River project was transferred from the Research Council on April 1, 1952.

Considerable expansion occurred in the work of the National Research Laboratories during the year, but especially in the field of defence production; new buildings are being erected to provide much-needed accommodation for several Divisions, and that for the Applied Chemistry Branch was expected to be occupied during the summer of this year. The largest outside unit now operated by the Council is the Prairie Regional Laboratory at Saskatoon. This is primarily concerned with research designed to promote new uses for agricultural products. Fundamental studies on the mechanism of the biosynthesis of ustilagic acid, a product of the corn smut fermentation, in which the fungus is grown in media containing radioactive carbon compounds, have been started, and many samples of ustilagic acid have been despatched for testing. Investigations on the control of loose smut of barley by treating infected seed with antibiotics are being continued. The carbohydrate metabolism of bacteria is being studied with radioactive carbon dioxide, and the concentration of the active carbon atom in the fermentation products shows that different organisms vary in their ability to incorporate carbon dioxide in their metabolic products. A new method has been developed for preparing radioactive cyanide, and fundamental studies in sugar chemistry were continued. The development of a rapid continuous process, which will produce a chemical pulp having properties similar to ball-milled straw, is being investigated and also the factors responsible for the increased resistance of these strawboards to water, while the fractionation of rape-seed oil with furfuraldehyde as solvent was being tested on a pilot scale.

Food investigations have had a major share in the Division of Applied Biology; but emphasis on long-term fundamental research is increasing. The Wiltshire bacon project was concluded with a study of the effects of varying temperatures and salt concentrations on storage life. Production of butylene glycol from beet molasses and sulphite liquor reached the pilot-plant stage, and a rapid method giving high yields of citric acid by the submerged fermentation of beet molasses has been developed in the laboratory. Studies in photosynthesis have shown that the Hill reaction is stimulated by anions at pH levels above the optimum, and that malic enzyme has a possible role in photosynthesis. Activity in the colloid section of the Division of Chemistry has been mainly concerned with the properties of suspensions, but the physical properties of anhydrous soaps have also been examined. The Division has continued its calorimetric investigation of the thermodynamic properties of simple gases adsorbed on solid surfaces; its study of the chemistry of liquid ammonia solutions; and its work on the thermal decomposition of gaseous organic compounds, using a mass-spectrometer, designed for the quantitative analysis of the stable products and of the short-lived intermediates, such as free radicals, which are formed. Investigations of critical-temperature phenomena have led to a better understanding of the nature of the liquid–vapour transition, and many measurements were made, in the project on the permeability of fabrics, of the air flow through wire gauze of varying fineness for different drops of pressure. The structures of all the alkaloids of the sparteine group have been established, and much attention given to the preparation of steroids containing deuterium.

In the Division of Applied Chemistry work on the simultaneous drying and thermal cracking of Alberta wet crude water-separated bitumen has given a cheap dry oil of low viscosity in a single operation. A very sensitive microbalance has been constructed for use in investigating the first stages of the oxidation of metals, and an automatic-recording balance has been designed and built to measure the oxidation-rates of heat-resistant alloys. A moisture-permeable white paint has been formulated for exterior use, and the adsorption of anionic- and non-ionic-type synthetic detergents has been studied on three types of carbon taken as representing the important components of normal 'dirt', and also their adsorption on textile fibres. Two new reactors with multi-point sampling and feed connexions have been built for the small-scale plant for the oxidation of ethylene to ethylene oxide to determine optimum conditions and flow design for a full-scale pilot plant.

The Canadian defence programme has particularly affected the Division of Mechanical Engineering, and assistance to industry in the design and development of new aircraft constitutes a large part of the work of the Division's aerodynamics and flight research laboratories. A thermodynamics laboratory was being constructed for work on compressors and gas turbines, and in the low-temperature laboratory work on aircraft-icing included measurement of the physical characteristics of icing-clouds and the development of electrothermal protection for aircraft wings, propellers, windscreens and tail units. The Division of Medical Research made special provision for research into the action and uses of adrenocorticotropic hormone and cortisone, under an *ad hoc* advisory committee, while under the regular research programme 125 grants-in-aid were made during 1951, including eleven for studies in arteriosclerosis or in cholesterol metabolism, a large grant to Dr. L. B. Jacques to study the clotting of blood, and nine for investigations bearing on the development of bone, the natural alignments and proportions of the bony skeleton and the reparative processes which follow damage.

---

* Thirty-fifth Annual Report of the National Research Council of Canada, 1951–52 (N.R.C. No. 2780). Pp. 46. (From the Council, Ottawa, 1952.)

In the Department of Physics the newly established laboratory to investigate the nature of the solid state is already undertaking work on thermal and electrical conductivity, the nature of superconducting materials and the study of specific heat and thermal dilatation, and much important preliminary work has been carried out in the new photogrammetric research laboratory. Studies of the factors involved in the reduction of the noise associated with the testing of jet engines, and of photographic resolution in contact printing have also been made by the Division. Apart from projects for the Armed Services, the Division of Radio and Electrical Engineering has completed a long-term study of the absorption of micro-wave radiation by snow and has continued studies on the fundamental aspects of electron emission from oxide-coated cathodes and on radio-frequency re-warming techniques for treatment of patients with lower body temperatures; it has developed further the micro-wave beacon system as well as a remote-control system for unattended fog-horn stations and also an experimental wired television system for viewing submerged objects.

SYNTHETIC ACTION OF ALMOND EMULSIN

By Prof. STANLEY PEAT, F.R.S., Dr. W. J. WHELAN and Mrs. K. A. HINSON

Chemistry Department, University College of North Wales, Bangor

THE literature contains numerous references to the synthetic action of α- and β-glucosidases. Thus Croft-Hill[1] claimed the synthesis of maltose from glucose by the action of a yeast extract. Bourquelot and Bridel reported the synthesis of β-glucosides by the action of almond emulsin (a β-glucosidase) on glucose and alcohols[2] and also the synthesis of gentiobiose by action on glucose alone[3]. These workers recognized that gentiobiose is not the sole product of this action, and suggested that cellobiose was also formed[4]. The products obtained by Croft-Hill were ill-defined[5]; but the synthesis of gentiobiose by emulsin is a well-established fact and is recommended as a preparative method for this disaccharide[6].

As part of a study of the synthetic activity of glucosidases, we allowed almond emulsin (0·6 gm.) to act on a concentrated aqueous solution of glucose (60 gm./102 ml. solution) at 35° for five weeks (under toluene). Paper chromatograms of the digest indicated that gentiobiose made its appearance within three days, and later revealed the formation of other synthetic products. After the incubation, the digest was fractionated on a charcoal-'Celite' column[7] and, following the removal of glucose, five products were obtained. One was a pure substance; the others were mixtures which were, however, completely separated into four pure sugars by further fractionation on charcoal and, in one case, on filter paper. Each product proved to be a disaccharide, and examination of the physical properties of each sugar and its β-octa-acetate identified the five substances as gentiobiose (β-1 : 6 link), cellobiose (β-1 : 4), laminaribiose (β-1 : 3), sophorose (β-1 : 2), and ββ-trehalose. The properties and approximate yields are listed in the accompanying table. The synthetic disaccharides have R_F values identical with those of authentic specimens.

Emulsin displays a group rather than an absolute specificity, inasmuch as it catalyses the hydrolysis of many β-glucosides, including the five disaccharides under discussion. It is evident that in its synthetic action the enzyme also displays group specificity. Each of the available hydroxyl groups in the glucopyranose 'acceptor' can be utilized for the formation of a β-linkage, although some selectivity appears to be exercised with respect to the α- or β-configuration of C_1 since αβ-trehalose has not been detected. It would seem that emulsin catalyses the reversible reaction:

$$\text{Glucose} + \text{glucose} \overset{\text{Emulsin}}{\rightleftharpoons} \text{disaccharides} + \text{water}.$$

The equilibrium does not lie completely on the side of hydrolysis, and the extremely slow rate of disaccharide formation suggests that the energy for synthesis is derived from the thermal motion of the molecules rather than from a chemical reaction. It is also reasonable to suppose that the relative yields of the disaccharides will be inversely related to the rates at which they are hydrolysed by emulsin. It is known, for example, that cellobiose is more readily hydrolysed by acid than is gentiobiose[12], and the table shows that the latter is preferentially synthesized. On this basis, the order of stability of the disaccharide links would be β, 6 > β, 4 > β, 3 > β, 2 or β, β. It may be mentioned that prolonged action of emulsin on glucose leads to the synthesis of saccharides of a higher order than the disaccharides described. These higher saccharides have not yet been examined. If the synthesis proceeds in the

random fashion displayed in the case of the disaccharides, there could be formed forty trisaccharides and four hundred and forty tetrasaccharides.

We believe this to be the first authenticated synthesis of cellobiose by enzymic action, and while it is highly improbable that cellulose is synthesized in plants by the action of a β-glucosidase on glucose, the fact that a β-1 : 4-link is synthesized by emulsin may not be without significance.

We wish to express our thanks to Dr. F. Cramer (Heidelberg) and Dr. G. H. Coleman (Wayne University, Michigan) for authentic specimens of sophorose and ββ-trehalose octa-acetate respectively.

FLIGHT-TONE AND WING-STROKE FREQUENCY OF INSECTS AND THE DYNAMICS OF INSECT FLIGHT

By Dr. OLAVI SOTAVALTA

Department of Zoology, University of Turku, Finland*

MANY methods have been employed for determining wing-stroke frequency in insects[1,2]. The kymograph was mainly used by the older authors[3-5], and the chronophotographic method has also been used by investigators of insect flight[6-8]. Modern investigators have successfully applied the stroboscope[9-15] and the oscillograph[2,16-17].

An isolated position is occupied by the acoustic method, which, like the oscillographic method, determines the wing-stroke frequency by the flight-tone, that is, by the hum emitted by a flying insect's wings. One of the first investigators of wing-stroke frequency, Landois, applied this method[18], and I also have used it[1,2]. Since no registering instrument is required, the technique is more or less subjective and must therefore be used under strictly critical conditions. The difficulties that an inexperienced or 'quasi-musical' observer will readily encounter include the 'soprano-tenor-error', which is of a psychological nature[1,2], and this has, unfortunately, produced a systematic error of one octave in the determinations of some of the earlier authors, including Landois himself. I have shown that the critical use of this technique will produce results fully consistent with those obtained by instrumental methods; and the agreement between the frequency of the wing-strokes and the flight-tone has recently been beautifully confirmed by Williams and Galambos with practically simultaneous stroboscopic and oscillographic observations on the flying insect[15]. Moreover, the acoustic method makes it possible to observe insects in free flight, while the other methods more or less limit observation to insects attached to a support.

The wing-stroke frequency, ranging in the insect world from 0 to about 1,000/sec., is found to have a certain relationship to the wing and body dimensions and to the wing-stroke angle of the insect[2]. In some insects (for example, among the Diptera) it varies, moreover, with the environmental temperature[2,9], while in others (for example, among the Hymenoptera) it is independent of this factor[2]. The results concerning the relationship between the frequency and the atmospheric pressure or density have hitherto been discrepant[2,18]. It has also been found that mutilation of the wings by cutting increases the wing-stroke frequency, though this fact has been given a variety of explanations[2,4,7,18,19].

Chadwick, Williams *et al.*[10-14] have shown that the wing-stroke frequency in *Drosophila* is an indicator of the consumption of energy by this insect, and is thus a method by which a quantitative approach to the dynamics of the flight of insects is possible. An investigation carried out in the Department of Zoology, University of Cambridge, during 1948–50[20] has shown that the wing-stroke frequency seems to indicate delicately the state of balance between the dimensions of the insect and the dynamics of its flight. When the wings of an insect are mutilated or loaded, the frequency of wing-stroke varies in inverse proportion to the cube root of the total moment of inertia of the wings, independent of whether the alterations are made symmetrically or asymmetrically on the two sides. When the insect is exposed to subatmospheric pressures, the frequency of wing-stroke is unaffected or shows a certain negative correlation with the pressure (actually, with the density[18]) of the gas medium, depending on the size and the frequency of wing-stroke of the insect.

In one series of experiments, the wings were mutilated by transverse, longitudinal or oblique cuts, or loaded with a drop of collodion. The moment of inertia (I) was calculated by approximate methods and the wing-stroke frequency (ν) determined mainly acoustically. The results were examined on a two-way logarithmic co-ordinate system, and showed the following relationship :

$$\nu \propto I^{-0 \cdot 33 \pm 0 \cdot 05}.$$

In another series of experiments, the insects were allowed to fly in a pneumatic bell-jar, connected with a water-jet pump. The atmospheric pressure (p) was read from the manometer and the frequency of wing-stroke determined mainly acoustically by aid of a microphone inside the bell-jar. The results were examined as above, and showed the following relationship :

$$\nu \propto p^{0 \to -0 \cdot 25},$$

the exponent depending on the size and frequency of wing-stroke of the insect

Considering the wings of an insect as bodies simultaneously performing simple-harmonic rotary motion and as paddles working against the air, and assuming (1) that the kinetic energy of the wings is destroyed after each single up or down wing-stroke, and (2) that the rate of energy output of the insect and the stroke-angle (φ_0) of the wings (that is, the amplitude measured) from the 'equilibrium' position remain constant, the energy used for keeping the wings in motion during a time t is calculated to be

---

* Present address: Department of Biology, Tufts College, Medford, Mass., U.S.A.

$$E_t = 2\pi^2\nu^2 I\varphi_0^2 \, . \, 2\nu t = 4\pi^2\nu^3 I\varphi_0^2 t,$$

$$\text{and therefore } \nu \propto I^{-0.33},$$

which very well agrees with the experimental results of the first series. The theoretical value of the amount of work done against the air[20,21] under the same conditions is estimated to be variable—less than 1 per cent of the work done in keeping the wings in motion, that is, against the effect of wing inertia, and therefore negligible, in insects of a large ('usual') size and a relatively high wing-stroke frequency, and more significant in insects with a small size and/or a low wing-stroke frequency. This fully agrees with the experimental results of the second series, and therefore also explains the inconsistency in the earlier results of the effect of atmospheric pressure or density on the frequency of wing-stroke.

If further experiments continue to support the theory advanced here, it follows that: (1) the energy economy in a big insect is very wasteful; (2) the rate of energy output does not vary greatly; (3) it is more economical for the insect to vary the aerodynamic work of the wings by altering the amplitude rather than the frequency; (4) the distribution of energy in flight is delicately balanced; and (5) the frequency must be low and the amplitude large in insects of a very large size, and that a very high frequency and a small amplitude can be afforded only by small insects. Many observations that have been made in Nature agree with these inferences. Attempts were also made to calculate the theoretical muscle efficiency of some insects.

Some laws relating to different morphological characters of the wings of insects have also been formulated, and in some cases a striking correlation is recorded between these characters.

Contrary to the assumption made here, Chadwick[11] has found that, in *Drosophila*, the amplitude shows a correlation with atmospheric density. However, as the amplitude in insects is generally relatively large, the percentage change in it cannot be so great as to produce distinct changes in the balance of other factors involved, such as those described in the present article.

That the mutilation of wings must be symmetrically equal on both sides before an effect on the wing-stroke frequency is observed has been claimed by Roch[5]. This conclusion has been proved wrong by the present author[2,20] and by Chadwick and Williams[13].

The earlier theories of the present author and others[1,18,21,22] relating the wing-stroke frequency to the dimensions of insects or to the dynamics of flight are therefore incomplete, since they neglect the effect of wing inertia; this, however, seems in most insects to be a major factor involved in the dynamics of flight.

Pringle[23] concluded that the main principle in the contraction of the flight muscles in flies was the existence of a non-reflex myogenic oscillation, the frequency of which is controlled by the direct loading of the flight muscles, and which continues so long as the requisite state of excitation is maintained by arrival of motor nerve impulses. He discovered that the nerve impulses recorded in the thorax arrived in a rhythm of one impulse to several wing-strokes; and Roeder's[17] observations that in the fly and wasp the changes of potential (arriving nerve impulses) in the thorax are not synchronous with the thorax movements, while in the moth and cockroach they are, extend this view. The observations presented here would also be in accord with the findings of these authors. [May 8.

EFFECT OF THE 'MARSH FACTOR' ON THE SHORTENING OF MUSCLE FIBRE MODELS IN THE PRESENCE OF ADENOSINE TRIPHOSPHATE

By J. R. BENDALL

Low Temperature Station for Research in Biochemistry and Biophysics, University of Cambridge and Department of Scientific and Industrial Research

In recent papers from this laboratory, B. B. Marsh[1,2] has described a factor present in extracts of fresh rabbit's muscle which inhibits the shrinkage of muscle fibres when treated with adenosine triphosphate (ATP) and also markedly inhibits the breakdown of adenosine triphosphate in a suspension of washed fibres. In view of the important physiological implications of these observations, they have now been extended to a study of the action of the factor upon strips of anatomically intact muscle, modified physiologically so as to render them suitable for demonstrating the action of the factor.

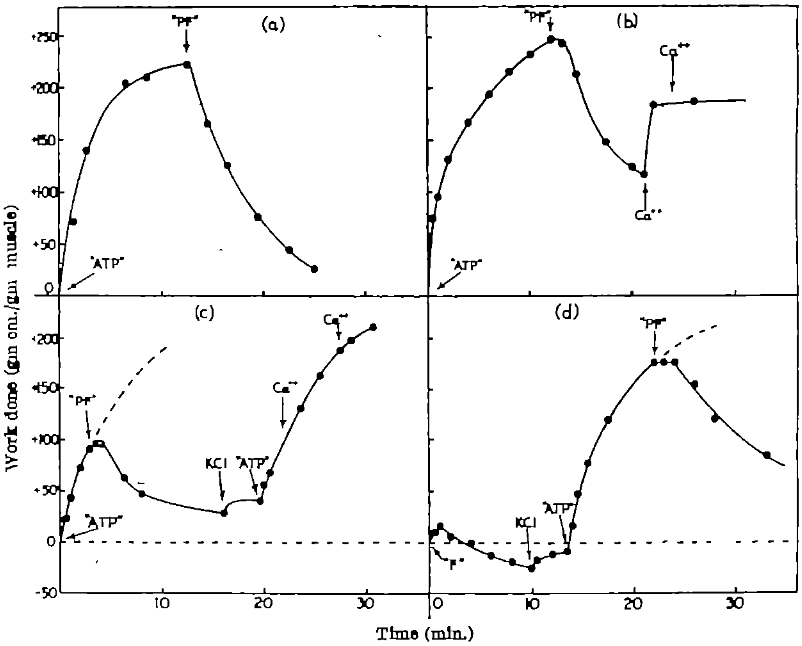
The first difficulty to be overcome was the preparation of a reasonably stable active extract, since, as Marsh showed, the active factor is extremely labile and is inactivated in a large number of cases without apparent cause. After many trials, it was found that an active extract could best be prepared from the psoas muscles of rabbits paralysed with myanesin for 15 min. before death by decapitation. The paralysis ensures a high *p*H (> 7·0) in the muscle[3]. Weighed samples of muscle are then minced with scissors into four volumes of 0·04 M potassium chloride with 0·004 M iodoacetate solution, and immediately homogenized in the Marsh–Snow homogenizer[4] for 1–2 min. The resulting brei is left 30 min. at room temperature to attain full chemical equilibrium and then centrifuged for 5–10 min. at 3,000 r.p.m. About 60 per cent of the original total volume is recovered as a slightly cloudy, opalescent extract. The potassium chloride concentration of the extract is then made 0·16 *M* by addition of 1·6 *M* potassium chloride, and the final solution is stored at 0° C. It is stable for at least 12 hr. The purpose of the iodoacetate in the extractant is to prevent glycolysis and to maintain a *p*H in the range 6·95–7·05. Marsh[3] showed that iodoacetate has no inhibitory effect on the activity of the factor under investigation.

Two methods were employed for preparing a model fibre system on which to test the factor extracts. The first of these (system 1) was a modification of a method of Perry[5], by which the psoas muscle of a rabbit, paralysed for 15 min. with myanesin before death, was exposed and from it were separated with a blunt scalpel thin strips, about 0·3 mm. thick. The strips were tied off with cotton thread at either end, the distance between the ties being 2·0–3·0 cm. The strip was then cut away, attached at one end to the bottom of a vertical muscle-bath and at the other to a light kymograph lever, and fixed at the rest-length. A solution of 0·9 per cent sodium chloride and 0·004 *M* iodoacetate was then run into the bath and left in contact with the strip until rigor had occurred (2–3 hr.). The solution was then run out, and the muscle-bath attached to the supporting column was removed to a room at – 20° C. for 24 hr. It was then brought back to room temperature and fixed in the kymograph machine, and a solution of 0·16 *M* potassium chloride with 0·005 *M* magnesium chloride added to the bath and left there for 10 min. before addition of adenosine triphosphate or Marsh factor.

The second method (system 2) was to prepare strips about 1½ mm. thick from a psoas muscle (as above), attach them to cork supports and submerge them in 50 per cent glycerol at 0° C. for 24 hr. (cf. Szent-Györgyi[6]). At the end of that time they were removed and strips 0·2–0·3 mm. thick were separated from them at 0° C. These were tied off with cotton at either end, the length between ties being 2–3 cm. The strips were then placed in 0·16 *M* potassium chloride with 0·005 *M* magnesium chloride solution, brought to room temperature, and placed in position in the muscle-bath. They were left in potassium chloride solution to attain osmotic equilibrium for 20 min., and additions of adenosine triphosphate or factor were then made. In both systems a gentle stream of nitrogen bubbles was used to stir the fluid in the bath.

Both types of preparation normally shorten under load on addition of adenosine triphosphate. (During a brief period in the spring, system 1 lengthened on addition of adenosine triphosphate and would only shorten on subsequent addition of calcium ions. This effect is as yet unexplained, but may be connected with membrane impermeability.) It was possible with the iodoacetate-poisoned frozen system (system 1) to make a full study of the relation between thickness of fibre-bundle and work done under optimal load and to show that the Webers's contention[7] was correct that only an outside ring of single fibres was fully reactive to adenosine triphosphate over a range of thickness of bundle of 0·2–1·0 mm. It has also been possible to study the effect of the Marsh factor upon it. Such an experiment is illustrated in Fig. *a*. At the first arrow a solution of 0·006 *M* adenosine triphosphate/0·16 *M* potassium chloride/0·005 *M* magnesium chloride was added to a strip 0·3 mm. in diameter. About 220 gm.cm. of work was done per gm. of muscle in 12½ min. under a load of 500 gm./sq. cm. At this point (second arrow) the adenosine triphosphate solution was run out and a factor preparation to which 0·006 *M* adenosine triphosphate had been added for 7 min. previously, was run into the muscle bath. The muscle immediately lengthened, and within another 12½ min. the load had done 195 gm.cm. of work upon it. This effect is typical of normal muscles in the presence of the factor preincubated with adenosine triphosphate. If adenosine triphosphate is added to the factor preparation and the latter then added immediately to the muscle there is a delay of 3–5 min. before lengthening begins.

Exactly similar results are obtained with glycerinated fibres (system 2). Curves of three-factor experiments with such fibres (system 2) are illustrated in Figs *b*–*d*. 0·006 *M* Adenosine triphosphate was used throughout, with or without the presence of the factor. Salt concentrations are as mentioned above for system 1. All the fibre samples were taken from the same glycerinated psoas strip. In addition, three control strips were studied under optimal loading conditions with adenosine triphosphate/



Effect of Marsh Factor preparation when added at various stages during the shortening of fibre-models in the presence of adenosine triphosphate. (*a*) Iodoacetate-poisoned frozen fibres (*b*)–(*d*) Glycerinated fibres
"ATP": 0·006 *M* adenosine triphosphate/0·16 *M* potassium chloride/0·005 *M* magnesium chloride.
"PF": Factor pre-incubated with 0·006 *M* adenosine triphosphate for 3–7 minutes as in text.
"F": Factor mixed with 0·006 *M* adenosine triphosphate and added to muscle immediately
Ca++ Addition of calcium chloride to 0·006 *M*.
KCl: Wash with 0·16 *M* potassium chloride/0·005 *M* magnesium chloride

potassium chloride/magnesium chloride solution alone. These are not shown, but they all shortened immediately on addition of adenosine triphosphate, and at thicknesses between 0·25 and 0·35 mm. gave an average work performance of 316 gm.cm./gm. of muscle in 13 min., with a range of variation of ± 35 gm.cm./gm.

In Fig. *b*, adenosine triphosphate/potassium chloride/magnesium chloride solution was added to the muscle at the first arrow. 250 gm.cm. of work was done in 12 min. At the second arrow a factor preparation pre-incubated with 0·006 *M* adenosine triphosphate for 7 min. was added. Immediate lengthening occurs, and 130 gm.cm. of work is done on the muscle by the load in 9 min. As calcium ions are known to inhibit[1] the increase of fibre-volume in the brei system, calcium chloride (final concentration 0·006 *M*) was added here (at the third arrow) while the factor was still present. The muscle immediately begins to shorten again, and in 4 min. does 40 gm.cm. of work. The curve then straightens out and addition of further calcium ions has no effect. This effect could also be demonstrated in system 1. However, addition of calcium ions only rarely brings about 100 per cent recovery from the lengthening caused by the Marsh factor. It is noteworthy that addition of calcium ions to the system shortening in adenosine triphosphate alone has little or no effect on the rate or amount of shortening (cf. the control curve in Fig. *c*, arrows marked Ca^{++}).

In Fig. *c*, the muscle was allowed to shorten in adenosine triphosphate solution to about half the maximum. At this point, pre-incubated factor was added (arrow 2), and immediately the rate of shortening slows down and within 1 min. the muscle begins to lengthen. This it was allowed to do for 13 min. Then, at arrow 3, the factor was washed out with a solution of potassium chloride/magnesium chloride. This brings about an immediate small shortening, indicating that some active part of the factor complex has been washed out of the muscle before all the adenosine triphosphate is removed. It is an invariable effect of washing with potassium chloride after factor addition. This was allowed to proceed for 3½ min., and then a fresh solution of adenosine triphosphate / potassium chloride / magnesium ions was added at arrow 4. This brings about its normal shortening effect. Addition of 0·006 *M* calcium chloride at arrows 5 and 6 brought about no change of rate, as mentioned previously.

In Fig. *d*, 0·006 *M* adenosine triphosphate was added to a factor preparation and the latter added to the muscle immediately. The muscle begins to shorten and do work, but after 1 min. the shortening ends abruptly and lengthening begins, proceeding almost linearly for 9 min., by which time the muscle has been stretched 5 per cent beyond its rest length. At this time the factor was washed out with a solution of potassium chloride/magnesium chloride (arrow 2) and again the muscle shortened slightly. When this shortening was complete (arrow 3), 0·006 *M* adenosine triphosphate/potassium chloride/magnesium chloride solution was added. Again the muscle shortens and does 185 gm.cm./gm. of work in 8½ min., which is a normal amount in this time. Then at arrow 4 a pre-incubated factor preparation (3 min. only) was added and lengthening sets in after a delay of 2 min.; 100 gm.cm. of work is done on the muscle by the load in 13 min.

All the experiments on addition of the factor and adenosine triphosphate to both model systems thus elicit a lengthening effect. Shortening, if it occurs in the presence of the factor, is of short duration and is followed by lengthening which, however, sets in without delay only if adenosine triphosphate is incubated with the factor for some minutes before addition to the system, thus indicating that time for the formation of the active substance or complex is needed. These results are therefore exactly comparable to Marsh's observations on breis, where addition of adenosine triphosphate to washed breis results in massive decrease of fibre-volume, but addition in the presence of an active muscle extract results in an increase of fibre-volume. The fibre-model system, however, has great advantages over the brei system both in speed of reaction and ease of observation, and is far closer to the physiological system.

Other outstanding similarities between the two systems are the effects of the addition of calcium ions in the presence of the factor and of lowering the ionic strength of the medium.

Addition of calcium ions invariably inhibits increase of fibre-volume in the brei system and lengthening in the fibre-model system, and immediately brings about a decrease in the former and shortening in the latter.

Extraction of the factor at low ionic strengths (for example, extraction with 4 vol. water) results in its temporary inactivation both in the brei and the fibre-model systems. However, addition of potassium chloride to 0·05–0·16 *M* to such an extract re-activates it.

It should be noted that the factor is inactivated by heating to 85° C. for 1½ min., and by holding at *p*H 4·0 for 5 min., as Marsh found. Dialysis, however, even for 48 hr. does not appear to result in loss of activity, at least with preparations at *p*H 6·80–7·10. Moreover, recent work has indicated that the undialysed preparations can be stored at 0° C. without loss of activity for much longer periods than was at first thought. Preparations have been found active after at least a week's storage. From these results it appears that the factor is a large non-dialysable molecule of protein nature, and is stable if stored under the conditions described.

The probable existence of a controlling factor of the nature described was postulated by Englehardt[8] as being necessary in the living muscle to prevent access of adenosine triphosphate to the contractile sites during relaxation and rest. The Marsh factor would fulfil this role, as its marked inhibitory effect on shortening in the presence of adenosine triphosphate and its lengthening effect on shortened muscle clearly show. In a full theory of contraction and relaxation in living muscle, however, the effect of the stimulus and of the subsequent action potential in evoking contraction would, in the light of these findings, have to be explained as at once an inhibition of the factor and an activation of the contractile sites.

The work described in this paper was carried out as part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research. [May 24.

APPARENT ANGULAR SIZES OF DISCRETE RADIO SOURCES

Observations at Jodrell Bank, Manchester

THE existence of discrete sources of extra-terrestrial radio-frequency radiation is now well established[1,2] and the positions of more than one hundred sources have been published[3–6]. Attempts to identify these sources with any particular class of visual object have so far failed, and the origin of the radiation remains unexplained. One of the fundamental requirements in the study of these sources is a knowledge of their apparent angular size, and although attempts to make this measurement have been made by several observers[1–5], it has proved to be beyond the resolving power of their equipment. The present communication gives a preliminary account of a successful attempt to measure the angular size of the two most intense sources the positions[6] and intensities[4] of which are given in Table 1.

Table 1. CO-ORDINATES AND INTENSITY OF THE TWO MOST INTENSE RADIO SOURCES

Source	Right Ascension epoch 1950	Declination epoch 1950	Intensity* at 81 Mc./s. (watts/sq.m./c.p.s.)
Cygnus	19h. 57m. 45·3s. ±1s.	N 40° 35·0′ ±1′	$13·5 \times 10^{-23}$
Cassiopeia	23h. 21m. 12·0s. ±1s.	N 58° 32·1′ ±0·7′	$22·0 \times 10^{-23}$

* The intensity given is twice that observed in one plane of polarization.

The co-ordinates are those given by Smith (ref. 6), and the intensities are those given by Ryle, Smith and Elsmore (ref. 4).

Previous measurements have been made with interferometers. Bolton and Stanley[1], using an interferometer mounted on a cliff and operating in a manner analogous to 'Lloyd's mirror', have shown that the apparent size of the source in Cygnus is less than 8 minutes of arc. More recently, Stanley and Slee[3], using a similar instrument, claim to have reduced this limit to 1½ minutes of arc. Ryle and Smith[5], using an instrument analogous to Michelson's stellar interferometer and with a base-line of 500 metres, have shown that the source in Cassiopeia has an angular size of less than 6 minutes of arc.

The resolving power of an interferometer depends primarily on the ratio of the wave-length to the base-line, and the limits quoted above represented the best performance obtained with the instruments. These limits cannot be reduced significantly without a corresponding extension of the base-line.

In 1950 it was decided at Jodrell Bank to attempt to measure the angular size of the two sources shown in Table 1, or at least to reduce the upper limits given for their size. It was assumed that this angular size might lie anywhere between the limit of a few minutes of arc and the diameter of the visible stars, and an instrument of the highest possible resolving power was therefore sought. While it appeared to be possible to extend the base-lines of existing interferometers to lengths of the order of 10–50 km., it was considered that for much longer base-lines the problem of maintaining an adequate stability of phase in the transmission of signals along the base-line would prove to be difficult. For this reason an interferometer of completely new design was developed.

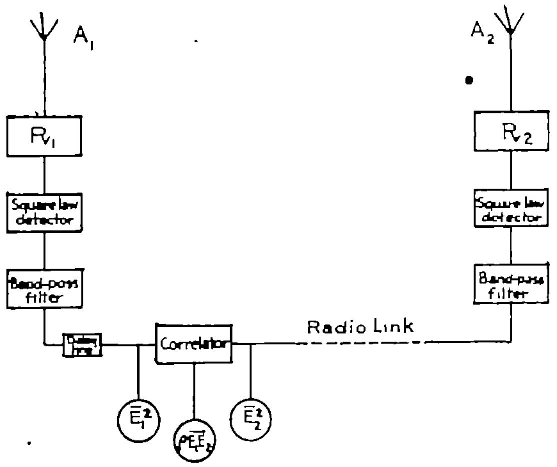

Fig. 1. Schematic diagram of the equipment

Fig. 1 shows a simplified block diagram of the instrument. Two aerial systems A_1 and A_2, each with an aperture of 500 square metres, are connected to two independent superheterodyne receivers R_1 and R_2. These receivers are both tuned to 125 Mc./s. and have a band-width of 200 kc./s. The intermediate frequency output of receiver R_1 is rectified in a square-law detector and is fed to a low-frequency filter the pass-band of which extends from 1 to 2 kc./s. The output from receiver R_2 is treated in an identical manner and the two low-frequency outputs are then multiplied together in a 'correlator' and their 'cross-correlation coefficient' is obtained. When a long base-line is used, one low-frequency output is transmitted over a radio-link by modulating a high-frequency carrier. The time of arrival of the two low-frequency outputs at the 'correlator' is equalized by inserting in one output a delay equal to the time of transmission along the base-line. It is essential that all the components should preserve the relative phase of the two low-frequency signals. In practice, this problem is considerably simpler than the corresponding one of preserving the relative phase of the

Table 2. EXPERIMENTAL RESULTS

Base-line			Cygnus		Cassiopeia	
	Length* (km.)	Bearing†	Correlation coefficient	Angular width of equivalent strip	Correlation coefficient	Angular width of equivalent strip
A	0·30	349·5°	0·99 ± 0·10	< 5′	0·96 ± 0·09	3′ 40″ (< 5′ 30″)
B	2·16	113·0°	0·30 ± 0·03	2′ 10″ ± 4″	0·08 ± 0·02	3′ 55″ ± 10″
C	2·16	235·5°	0·79 ± 0·08	1′ 00″ ± 7″	< 0·01	≮ 3′ 30″
D	3·99	177·0°	0·79 ± 0·07	0′ 34″ ± 8″	0·07 ± 0·01**	

* The value given is the actual distance between the two stations. The effective length of the base-line is calculated from the elevation of the source and the orientation of the base-line.

† The bearing is measured east from north, and is the relative bearing of the base-line from the fixed station at Jodrell Bank.

** This value is not taken into account in Fig. 3, since the other results indicate that the point may lie on a secondary maximum of the curve relating correlation coefficient to base-line.

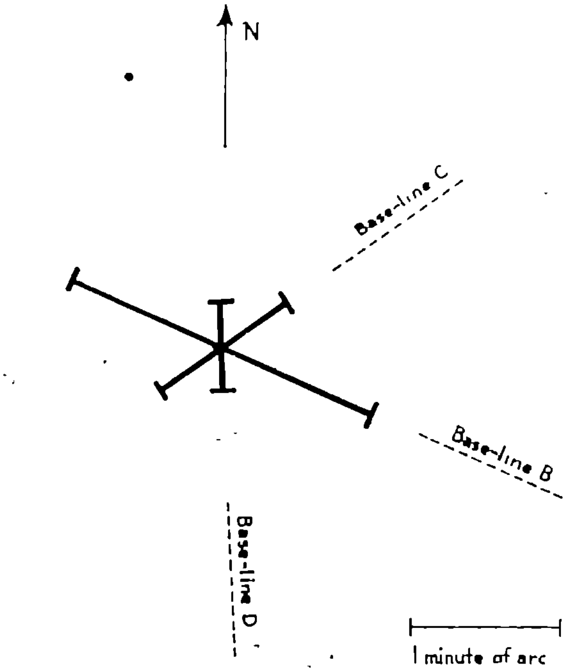

Fig. 2. Equivalent angular width of the source in Cygnus observed from different base-lines. The value shown is the width of an equivalent rectangular strip of constant surface intensity

radio-frequency signals in a conventional interferometer, and hence it should be easier to use the new type of instrument with long base-lines.

In operation, the two aerials (A_1 and A_2) are fixed in azimuth (due north or south) and at an elevation corresponding to the declination of the source. As the source transits the aerial beam, the increase in the mean square value of the two low-frequency outputs ($\overline{\varepsilon_1^2}$ and $\overline{\varepsilon_2^2}$) is recorded together with their product ($\rho\,\overline{\varepsilon_1\varepsilon_2}$). The value of the 'cross-correlation' coefficient' (ρ) is then found from an analysis of the three records.

The theory of the instrument is involved, and it will be given in detail elsewhere[7]. It can be shown that the value of the cross-correlation coefficient (ρ) is given by an expression similar to that for the visibility of the fringes in a Michelson stellar interferometer:

$$\rho = \frac{\sin^2(\pi\alpha b/\lambda)}{(\pi\alpha b/\lambda)^2}, \qquad (1)$$

where α is the angular width of an equivalent rectangular source of constant surface intensity; b is the effective length of the base-line; and λ is wave-length.

Equation (1) shows that by a suitable choice of the base-line it is possible to obtain a value for the angular width of an equivalent rectangular source of constant surface intensity. The shape and angular width of the actual source, together with the distribution of brightness across its disk, can only be found from a large number of observations made with base-lines of different length and orientation.

A model of the instrument, built in 1950, was used to measure the apparent diameter of the sun at 125 Mc./s. As the results of this test were satisfactory, a full-scale instrument was built in 1951, and this has since been applied to the two sources shown in Table 1. Measurements have so far been made on both sources with four different base-lines and the results are given in Table 2. The length and orientation of the base-lines are given in the table, together with the observed values of the cross-correlation coefficient (ρ). The angular size of the equivalent rectangular strip has been calculated for each base-line and the results are also shown in Table 2.

The interpretation of these results in terms of the precise actual size and shape of the sources must be treated with caution, since the three extended base-lines differed in length; and until more results are available it is uncertain what effect variations in the length of the base-line may have on the equivalent angular size of the source.

Figs. 2 and 3 show a plot of the measurements given in Table 2. Fig. 2 shows clearly that the source in Cygnus exhibits a pronounced asymmetry. The value of its equivalent angular size varies from 35″ to 2′ 10″ of arc with the orientation of the base-line, and the major axis of the source appears to be inclined at an angle of between 90° and 120° to the celestial meridian. A preliminary analysis indicates that the results are incompatible with a source of simple elliptical shape and constant surface intensity, and that a more complicated model must be used. Further progress in this analysis must await more observations. The results in Fig. 3 suggest that the source in Cassiopeia is not markedly asymmetrical. The equivalent angular size of the source appears to be about 4′ of arc.

These preliminary measurements establish two major points. First, the apparent angular size of the two most intense radio sources is thousands of times greater than that of the visible stars and is of the order of a few minutes of arc. Secondly, the source in Cygnus exhibits a pronounced asymmetry

in angular size, whereas the source in Cassiopeia appears to be roughly symmetrical. The measurements are not yet adequate to define satisfactorily the shape of the sources or the distribution of intensity across their disks. Further observations are now being made with the present apparatus, using different base-lines, and the results will be published later.

The work was carried out at the Jodrell Bank Experimental Station of the University of Manchester. The construction of the apparatus was made possible by a grant from the Department of Scientific and Industrial Research. We wish to thank Dr. R. Q. Twiss for his assistance with the mathematical theory, and Prof. A. C. B. Lovell for making the necessary facilities available and for his interest in the investigation. One of us (R. H. B.) is indebted to Messrs. Imperial Chemical Industries for a fellowship, and one (M. K. D. G.) to the Government of India for a scholarship and to the Department of Scientific and Industrial Research for a maintenance grant.

Observations at Sydney

The first observers of the discrete sources of cosmic noise were unable to determine their size, and many considered that they might be of stellar dimensions. However, recent observations have shown that a number of these apparently 'point' sources have angular extensions of the order of $\frac{1}{4}^\circ$ [1-3]. Position measurements have also suggested that the stronger sources might be identified with nebulæ of an angular size ranging from half a minute to several minutes of arc[3,4,5].

In order to check the hypothesis that the discrete source radiation originates in nebulæ rather than in individual stars, an interferometer with a lobe spacing as small as 1 minute of arc was considered necessary. At a frequency of 100 Mc./s., which is convenient because small low-gain aerials may be used, a Michelson-type interferometer requires an aerial separation of 10 km. to achieve this resolution. Such an interferometer was constructed using one small, easily portable aerial and one large fixed aerial. The signal from the portable aerial is transmitted back to the main receiver by a radio link. A simplified diagram of the equipment is shown in Fig. 1.

The local oscillator frequency must be transmitted together with the converted signal, as it is necessary to preserve the phase of the reconstituted signal at the receiving end of the link. Also a time-delay must be inserted in the signal-path from the fixed aerial to equalize the propagation times from each aerial to the mixing point. This time-delay is obtained with a mercury-filled acoustic delay line. Automatic gain controls are used to ensure equality of the signal-levels from each aerial and pre-amplifier system before they are combined in the receiver. The equipment has shown a variation in sensitivity of about 15 per cent over the period of six months that it has been in operation.

Preliminary measurements have been made on the four most intense sources observable from Sydney with various aerial spacings in an east–west direction. With the range of aerial spacings used, the four sources show a reduction in the amplitude of their interference patterns as the aerial spacing is increased, indicating that all four sources have been resolved by the equipment. The effects of aerial separation on the amplitudes of the interference patterns are summarized in Table 1.

Table 1

Aerial spacing	0 29 km.	1 02 km.	5·33 km	10 01 km.
Relative amplitude of interference pattern for Cygnus A	1	1	0 3	0 05
Taurus A	1	0·55	*	*
Virgo A	1	0 4	*	*
Centaurus A	1	0 3	*	*

* In these cases the amplitudes of the interference patterns were less than the noise fluctuations of the equipment and could not be observed. The relative amplitudes are less than 0·1–0 2

The probable errors in the relative amplitudes are thought to be about 10 per cent. The errors will be discussed in detail elsewhere; but it is worth mentioning one potential source of error. This is phase instability in the equipment and propagation link. It was checked using 101 Mc./s. transmissions from a small transmitter, which were received by both aerials and compared in phase at the mixing point. The resulting error was found to be negligible.

An inspection of the table reveals that the amplitudes of the Taurus A, Virgo A and Centaurus A sources are all significantly reduced with an aerial spacing of 1 km., whereas a spacing of 5 km.

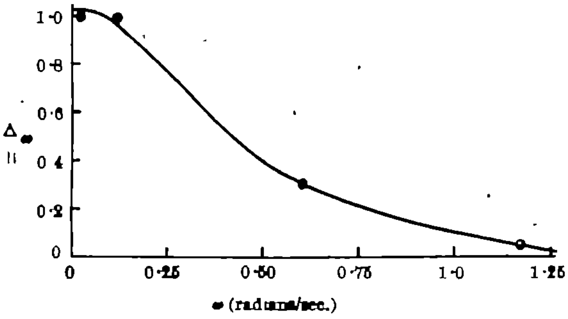
is required to produce a comparable reduction in the amplitude of the Cygnus source. The first-mentioned sources are all, therefore, of similar size and approximately five times the size of Cygnus A.

It has been shown that the amplitude and phase of the interference pattern produced by a source when observed with a given aerial spacing is related to the radio brightness distribution across the source by a Fourier transform[6] (the brightness being measured as the integrated emission across a strip at right angles to the interferometer axis). Thus, if the amplitudes and phase angles are known at a sufficient number of spacings, the brightness distribution may be obtained by Fourier synthesis. In the case of an interferometer with an east–west axis as we have here, this synthesis is given by

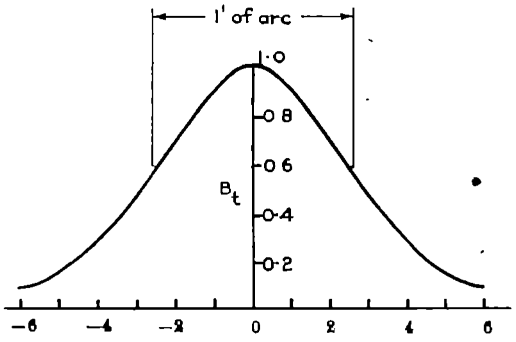
$$B_t = \int_0^{\sigma} A_\omega \cos\,(\theta_\omega + \omega t)\, d\omega,$$

where B_t is the brightness distribution in right ascension in arbitrary units, ω denotes the pulsatance of the sinusoidal interference pattern, corresponding to the aerial spacing, and A_ω and θ_ω the amplitude and phase of the pattern.

The present interferometer cannot be easily adapted to measure phase, so that the true distribution B_t is not easily obtained. If, however, the distribution is assumed to be symmetrical, θ_ω is then zero and an 'equivalent symmetrical distribution' can be obtained. This equivalent distribution is merely the cosine transform of the amplitude–pulsatance spectrum.



(a) Amplitude–pulsatance spectrum of Cygnus *A*



(b) Derived equivalent brightness distribution across Cygnus *A*

Fig. 2

For the Cygnus source we have four points from which to determine this spectrum. In Fig. 2(*a*) these points are shown and a smooth curve is drawn through them. Because of the absence of observations in the region between 1 and 5 km., there is some uncertainty in the exact shape of the curve, but its general features are clear. The equivalent brightness distribution corresponding to this spectrum is shown in Fig. 2(*b*). Because of the uncertainty in the spectrum, there is a corresponding uncertainty in the shape of this curve, particularly with regard to the skirts.

In the case of the other sources, there are not enough points to determine the spectra; but, if the reasonable assumption is made that their brightness distributions are similar to that of Cygnus A, it is possible to estimate their sizes. Defining an 'effective' size as the angle between half-brightness points on the equivalent distribution curve, we have the results of Table 2.

Table 2

Source	Effective size (E–W) (minutes of arc)
Cygnus A	1 1
Taurus A	4
Virgo A	5
Centaurus A	6

The size of the Centaurus source has been given previously as about $\frac{1}{3}$°[1,2]. It has been shown, however, that it consists of an extended source of nearly 2° in size with a strong concentration near its centre[3]. The size quoted in Table 2 is that of the central concentration. Measurements with very close spacings have confirmed the interpretation in terms of two apparently quite distinct contributions.

The four sources have been found to have positions very close to nebulæ, and it is now found that their angular sizes are comparable with those of the nebulæ in question. We may therefore say that the suggested identifications of the four sources concerned have been strengthened, almost to the point of certainty. The confirmation is particularly welcome in the case of Cygnus A, as when it was first pointed out that this nebula was near the radio position of the source[4] it appeared to be a typical galaxy, too faint to be responsible for the radiation. Minkowski has now shown, however, that it has very peculiar features (personal communication). Taking these sources in conjunction with the others for which angular sizes have been obtained, there is now strong evidence that the discrete sources are largely, if not entirely, nebulæ. Both galactic and extra-galactic nebulæ have been identified.

This work is continuing and will be described in more detail elsewhere.

Observations at Cambridge

At the recent meeting in Sydney of the International Union of Scientific Radio, reports were given of three separate experiments designed to measure the angular diameter of radio stars by the use of interferometers of large resolving power. Two of the experiments, by Hanbury Brown and by Mills, have been extended and are the subject of the present communication. The third, carried out at Cambridge in the first half of this year, has been described elsewhere[1]; since a rather different range of apertures was used in this experiment, it is thought appropriate to describe the results briefly for comparison with the other accounts.

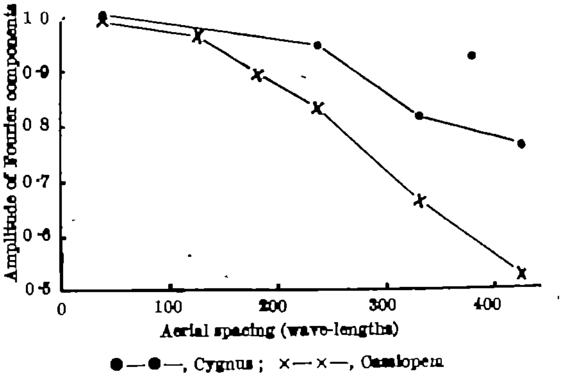
It was first pointed out by McCready, Pawsey and Payne-Scott[2] that interferometer aerials could be used to determine the angular distribution of radio 'brightness' across a source of radio waves. They showed that this distribution could be resolved into Fourier components by the use of different aerial spacings. The application of this principle to the determination of the distribution of radio brightness across the sun has already been described[3,4]; it was shown that a determination of the complete variation of the amplitude of a recorded signal as the aerial spacing was changed allowed the radial distribution of a circular source to be derived.

Similar observations have been made in an attempt to determine the distribution of brightness across the intense radio stars in the constellations of Cygnus and Cassiopeia. Owing to the smaller angular diameter of these sources, it was necessary to determine the amplitudes for the smaller spacings with considerable accuracy. It was not possible to determine the whole amplitude spacing curve with the maximum aerial separation available; the fine structure in the distribution of radio brightness across the source could not, therefore, be determined.

In these observations, which were made at a wavelength of 1·4 m., the phase-switching method of detection[5] was used with aerials spaced along an east–west line up to distances of 400 wave-lengths. This method of detection allows the use of pre-amplifiers at the aerials and, therefore, enables large spacings to be used without difficulties due to the attenuation in the transmission lines. In order to avoid the necessity for long-term stabilization of the gain of a movable aerial system, a new system of observation was devised in which measurements were made of the ratio of the amplitudes of the records obtained with two different aerial spacings. These two spacings were obtained by using the movable aerial alternatively with two fixed aerials, and it was then no longer necessary for its gain to remain constant. Each observation then provides a measure of the ratio of two Fourier terms; although it was not possible to derive the separate Fourier components uniquely from the results of these experiments, a fair approximation to the actual curve of Fourier components could be derived. The results obtained by this method are therefore comparable with those obtained in the two other methods; and although the present method cannot conveniently be used to make measurements at very great apertures, it has advantages for determining the Fourier terms related to the larger-scale structure of the brightness distribution.

MEASURED RATIO OF FOURIER COMPONENTS

Aerial spacing in wave-lengths		Cygnus	Cassiopeia
87	423	0·79 ± 0 05	0·62 ± 0 05
131	330	0·83 ± 0 02	0 70 ± 0 02
36	234	0·94 ± 0 03	0·84 ± 0 02
13	186	—	0·92 ± 0·03
75	124	—	0·97 ± 0·02



Measured Fourier components of the distribution of radio 'brightness' across the radio stars in Cygnus and Cassiopeia

The results of the Cambridge observations on the radio stars in Cygnus and Cassiopeia are shown in the accompanying table.

A possible interpretation in terms of Fourier components is shown in the diagram.

The measurements are consistent with those to be expected from a uniformly bright disk of 3·5′ diameter for Cygnus, and 5·5′ diameter for Cassiopeia. The measurements at larger resolving powers reported at the Sydney meeting of the International Union of Scientific Radio by Hanbury Brown and by Mills showed that there is also some structure of smaller angular width, and that there might be some considerable departure from circular symmetry. It is of interest to compare these results with those that might be expected from the visible nebulæ which have been identified with those two radio stars (Baade and Minkowski, in course of publication).

The Cygnus nebula is extragalactic. It has a central concentration about ¼′ of arc across, surrounded by a more diffuse region. The nebula is faint, so that it is difficult to estimate the extent of this region, but it is at least 2′ of arc in diameter.

The Cassiopeia nebula is a gaseous nebula in which the brightness is distributed unevenly over a roughly circular region about 5′ of arc in diameter. There are some particularly bright regions concentrated in an area extending 2′ of arc east–west and 1′ of arc north–south.

It appears that the radio measurements are in good agreement with the brightness distributions which might be expected from these nebulæ; this conclusion further strengthens the evidence for their identification with the two radio stars.

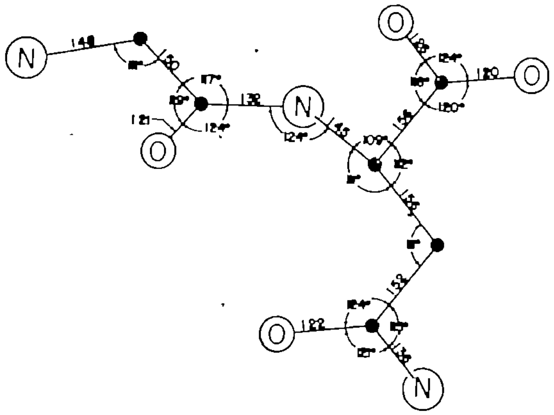
Configuration of the Peptide Link and of Asparagine in Glycyl-L-Asparagine

Since the geometrical problem of protein structure is mainly that of the configuration of the polypeptide chains, the geometry of the peptide link itself is a matter of prime importance. However, very few crystal-structure data have yet been published from which precise dimensions of the peptide link may be derived. We have recently carried out a three-dimensional X-ray analysis of the structure of glycyl-L-asparagine which provides an additional source of these data. Our analysis also provides information concerning the molecular configuration of asparagine, an amino-acid the structure of which has recently been discussed in *Nature* by Steward and Thompson[1].

The crystal data for glycyl-L-asparagine are: density, 1·506 (by flotation); space group, $P2_12_12_1$ (orthorhombic); unit-cell dimensions, $a = 4·81$, $b = 12·85$ and $c = 13·52$ A.; number of molecules per unit cell, 4. The intensities of all observable copper $K\alpha$ reflexions (more than a thousand) were estimated visually. These data were used to prepare a sharpened three-dimensional Patterson synthesis, from which, aided by application of the vector convergence method[2,3], we were able to deduce a satisfactory model for the molecule. Refinements of the thirty-nine positional parameters (excluding hydrogens) were made by using two- and three-dimensional Fourier synthesis and least squares methods. Most of the calculations were carried out with I.B.M. machines. The average standard error in the final parameters is 0 010 A.

The molecule of glycyl-L-asparagine (see diagram) can be described most simply by reference to two planes approximately at right angles to each other. One plane contains the succinamic acid part. The other contains the five atoms of the peptide group; the C—N bond to the amino-nitrogen atom points 8° out of this plane. One carbon atom is common to both planes. As is found in other amino-acids and peptides, the molecule of glycyl-L-asparagine contains the charged groups $—NH_3^+$ and $—COO^-$.



A drawing of the molecule of glycyl-L-asparagine viewed along the *a*-axis of the crystal. Bond-lengths are given in angstroms

The dimensions of the peptide (see diagram) agree, within the limits of error of the structure determination, with those postulated by Pauling and Corey[4] in their models of proteins. In particular, their assumption of planarity for the peptide group is supported, since we find the average distance of the atoms from a plane to be 0·002 A. The atoms of the asparagine residue, excluding its α-amino-nitrogen atom, form a nearly planar extended chain. Thus, our structure does not conform to the cyclic structure proposed by Steward and Thompson[1] for free asparagine, and visualized by them as a possibility also when the molecule occupies the terminal position at the carboxyl end of a peptide chain.

There is a significant difference in the lengths of the C—O bonds of the carboxyl group. This difference is consistent with the distribution of hydrogen bonds; the oxygen atom of the longer bond participates in three N—H···O bonds, the other oxygen atom in only one. The carboxyl group is co-planar as expected. The same is true of the terminal amide group, and its bond-lengths are close to those found in the peptide amide group. However, the bond-angles around the carbon atom of the terminal amide group are significantly different from the corresponding angles in the peptide amide group; their magnitudes are reminiscent of those reported for the molecule of acetamide[5].

Of the six possible hydrogen bonds, five are found to have satisfactory lengths (2·75–2·93 A.) and bond-angles. The sixth, which involves the amino-nitrogen atom, has a length of 2·99 A. but is open to question, because its angles with the other H-bonds deviate appreciably from the tetrahedral.

We wish to thank Dr. John Leonard for the preparation of the glycyl-L-asparagine and for his assistance in reading the intensities. We are indebted to Dr. Jerry Donohue for valuable discussions and for instruction in the I.B.M. computing techniques.

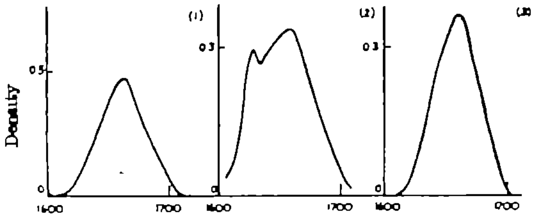
Behaviour of a Synthetic Polypeptide analogous to Protein Denaturation

Some observations made recently in this laboratory suggest a considerable resemblance, in certain respects, between poly DL-alanine and the soluble form of silk obtained from solution in cupriethylene diamine or lithium bromide solution[1,2].

Poly DL-alanine (degree of polymerization estimated from end-group analysis, about 500) is readily soluble in cold water, giving a mobile solution from which coherent films may be cast. The infra-red spectrum of these films (Fig. 1) shows a single C=O stretching mode at 1,662 cm.$^{-1}$, the frequency corresponding to a folded polypeptide chain[3]. If the solution is heated, a gel quickly separates out; this gel is not redissolved



Infra-red spectra of dried poly DL-alanine films. (1) Cast from aqueous solution at room temperature, (2) cast from boiled aqueous solution (gel), (3) cast from gel dissolved in formic acid

on cooling. A gel is also formed if the solution is kept at room temperature for several weeks. The spectrum of the dried gel (Fig. 2) shows a distinct additional peak of 1,629 $cm.^{-1}$, corresponding to the frequency of an extended (β) polypeptide chain. The dried gel is soluble in formic acid, and the film cast from this solution is water-soluble and shows only the 1,662 $cm.^{-1}$ peak (Fig. 3); this shows that the polypeptide has been taken through a cycle back to its original condition.

An alternative method of changing the water-soluble film to the insoluble form containing a proportion of extended chain is to roll it out. In this case, the β-material is oriented and measurements with polarized infra-red radiation confirm, from the type of dichroism observed, that the 1,629-$cm.^{-1}$ band is associated with an extended chain.

Another point of interest was observed during experiments on the effect of deuteration on poly DL-alanine. It was found that the polymer goes much less readily into solution in D_2O than in H_2O. In view of the complication of the α–β transformation, it is not certain at present what significance is to be given to this observation.

It is evident that in poly DL-alanine the equilibrium between α- and β-forms is very nicely balanced, and the transition from one to the other is readily induced. A similar state of affairs is known to exist in the soluble form of silk which in aqueous solution sets to a gel after some days, and which in the solid may be rendered insoluble by mechanical treatment[1]. Changes in the C=O band similar to those here reported accompany the insolubilization of silk[2].

Changes in synthetic polypeptides from α- to β-forms have been described before[3-5], but this is the first case in which the change can be brought about in aqueous solution, or by mechanical working at room temperature, earlier examples being produced by the action of formic acid, or by stretching in steam. It was an unexpected result that poly DL-alanine dissolved in formic acid gives an α-film, for this reagent, in the case of several polypeptides, produces a change from α- to β-configuration. However, it is highly satisfactory that a synthetic polypeptide exists which is capable of changes which are so reminiscent of denaturation and renaturation of proteins. In this case, there is no complication of active side-chains which, in proteins, may complicate the effect of various processes on solubility. The results speak strongly for the view[6,7] that an α–β transformation is often involved in protein denaturation.

It would be of great interest to know whether the α–β change in poly DL-alanine ever goes to completion, and, if not, why. It must be remembered that in a racemic chain there may be a succession of D- (or of L-) residues, whereas in other parts the order may be —D—L—D—L—. Such differences in the succession may be significant in a system like poly DL-alanine, and some parts of the chain may change over to the extended form more readily than others.

I am greatly indebted to Mr. W. E. Hanby, Dr. S. G. Waley and Dr. J. Watson for samples of poly DL-alanine, and to Mr. G. Ingram for the end-group analyses.

The Hydrogen-Oxygen Reaction Sensitized by Nitrosyl Chloride

In studies[1] of the explosions of mixtures of hydrogen and oxygen sensitized by nitrogen peroxide and nitrosyl chloride, the following reactions have all been suggested as chain-initiating steps.

$$NO_2 \rightarrow NO + O \tag{1}$$

$$NOCl \rightarrow NO + Cl \tag{2}$$

$$NO + O_2 \rightarrow NO_2 + O \tag{3}$$

We have devised experiments which appear to give a direct demonstration that nitric oxide is concerned in generating centres.

A cylindrical 'Pyrex' vessel was built with a 'multiple-entry' tube centrally disposed (Fig. 1). The dead space, including the Bourdon spoon gauge, was made less than 6 per cent of the volume of the vessel by inserting the solid rod; at the same time the entry tap could be of wide bore.

In the first series of experiments, comparisons were made at 360° C. between the behaviour of mixtures of nitrosyl chloride, hydrogen and oxygen made up (*a*) outside the vessel, and then admitted, and (*b*) with the nitrosyl chloride put into the reaction vessel for a definite time, and the premixed hydrogen and

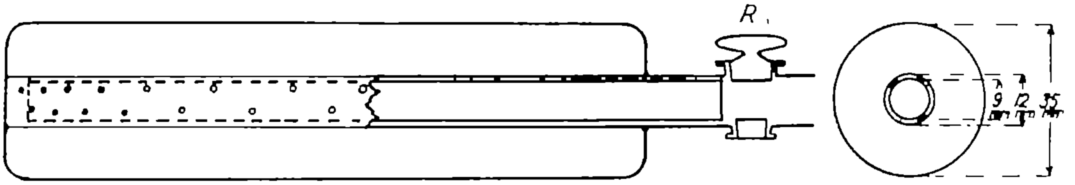

Fig. 1. Annular reaction vessel with multiple entry tube

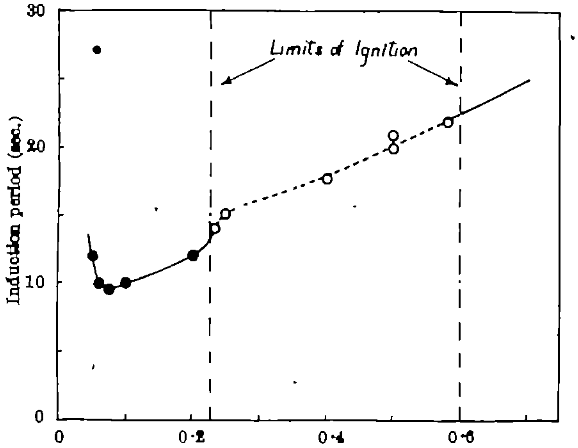

Fig. 2. Variation of the induction period with pressure of nitrosyl chloride, for 120 mm. of hydrogen and 60 mm. of oxygen at 360° C. Ignition between the limits, ----; slow reaction outside the limits, ———

oxygen then run in to give the same total pressure as in (*a*), namely, 120 mm. of hydrogen and 60 mm. of oxygen. With method (*a*) the results previously reported were confirmed; the existence of upper and lower sensitizer limits, and the trend of induction periods were as expected, as is shown in Fig. 2. With method (*b*), however, the induction periods between admitting the hydrogen and oxygen and the onset of ignition were considerably shortened. Fig. 3 shows a typical set of results, and it will be noticed that the induction periods become zero with quite short times of decomposition of the nitrosyl chloride.

In the second series of experiments, nitric oxide was put in the reaction vessel, and hydrogen and oxygen mixtures were run in, first without, and then with, traces of nitrosyl chloride, to give a total pressure of hydrogen and oxygen of 180 mm. With nitric oxide in the vessel and no nitrosyl chloride with the reactants, instantaneous ignitions were observed with all the pressures of nitric oxide used, from 0·25 mm. up to 10 mm. If there is an upper sensitizer limit under these conditions, it is extremely high. However, when sufficient nitrosyl chloride was run in with the reactants, the ignitions were suppressed; with smaller quantities of nitric oxide and

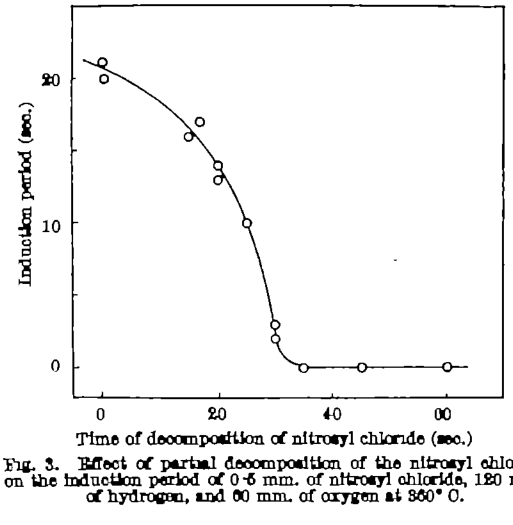

Fig. 3. Effect of partial decomposition of the nitrosyl chloride on the induction period of 0·5 mm. of nitrosyl chloride, 120 mm. of hydrogen, and 60 mm. of oxygen at 360° C.

In reaction vessel at 360° C.	Run in with hydrogen and oxygen	Induction period
0·25 mm. NO	—	Instantaneous ignition
0·50 mm. NO	—	Instantaneous ignition
0·25 mm. NO	0·25 mm. NOCl	17 sec.
—	0·50 mm. NOCl	20 sec.
—	0·50 mm. NO	10 sec.
0·50 mm. NO	0·50 mm. NOCl	No ignition

of nitrosyl chloride in the reactants, the induction periods reappeared before ignition. The accompanying table gives examples of these results.

In considering the relation of these facts to previous work[1], it is important to note that evidence has recently been obtained[2] that the rate of decomposition of nitrosyl chloride is much faster at temperatures above 300° C. than would be predicted from studies[3] of the decomposition at lower temperatures.

The experiments establish that a reaction of nitric oxide, such as (3), is concerned with an initiation step in the reaction between hydrogen and oxygen sensitized by nitrosyl chloride, and that the chief function of nitrosyl chloride is as a chain terminator. They suggest that part of the induction period is the time required for the nitrosyl chloride to decompose, yielding nitric oxide. In these respects, nitric oxide and nitrosyl chloride appear to play a similar part in the hydrogen – oxygen – nitrosyl chloride and in the hydrogen – chlorine – nitrosyl chloride systems[3].

We wish to thank Prof. R. G. W. Norrish and Prof. F. S. Dainton for many helpful discussions.

Determination of the Velocity of Burning

In a recent paper by Linnet and Conan[1], it is pointed out that the *Schlieren* cone is better suited for determining the velocity of burning than the luminous flame cone and the shadow cone. The *Schlieren* cone lies closer to the centre, as has been demonstrated by Broeze[2] and by others. Consequently, the deflexion of the outflowing gas through the combustion wave is considerably smaller at the *Schlieren* cone than at the luminous cone. Linnet and Conan justly remark that the cone at which the above-mentioned deflexion starts (which lies still deeper in the flame) is the most suitable for determining the velocity of burning. However, they did not recognize such a cone. I suggest it can be made visible by a phase-contrast photograph[3]. In order to attain this, the diffraction images of the light source are not intercepted in the focal plane *F* (see Fig. 1), as is done when applying the *Schlieren* method. Instead, the central image of this light source is changed in phase by 90° with respect to the diffraction images. Zernike[3] developed this method for the microscope. Calculations by Zernike show that the phase-contrast image is identical in structure and intensity with the gradients of the refractive index in the object (that is, the flame zone).

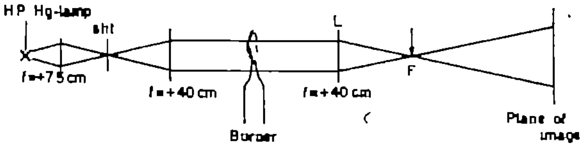

Fig. 1. Optical system for photographing *Schlieren* or phase-contrast cones
↓ Razor or phase strip. This must be placed exactly at *F*, as otherwise the plane of image is not uniformly illuminated if there is no flame interposed

By the *Schlieren* method, on the contrary, an image is obtained which does not give an absolutely correct representation of the object if there are steep gradients, owing to a relatively small contribution of diffraction images of higher order to the formation of the image.

This is expressed by the fact that velocities of burning determined with the *Schlieren* cone and those determined with the phase-contrast cone do not show the same values, as can be seen from Fig. 2. At the maximum velocity of burning (when the gradient is steepest) the divergence of the curves is greatest.

As structurally the phase-contrast image is identical with the gradient in the object, the starting point of the flame zone must coincide with the starting point of the deflexion of the outflowing gas. In Fig. 3 this is demonstrated by a photograph of the flame cone itself, taken together with a phase-contrast photo. A flow line (made visible by titanium chloride smoke) indicates the course of the outflowing gas.

Consequently, we must determine the velocity of burning with the help of the inside of the phase-contrast cone. In order to eliminate disturbing influences from base and tip, it is desirable to apply nozzle flow and use the middle part of the cone. This middle part must, in this case, show a straight generatrix. So long as no extremely poor or rich mixtures are used and the outflow velocity is sufficiently high, this is always realizable. With mixtures having extreme mixing ratios, deviations are caused by diffusion normal to the flow tubes[4]. Consequently, in this case we have to put up with a mean value over a certain length of cone.

The flame front selected in this manner is the only one which, both in the application of the surface method and of the angle method, gives the same value of the velocity of burning.

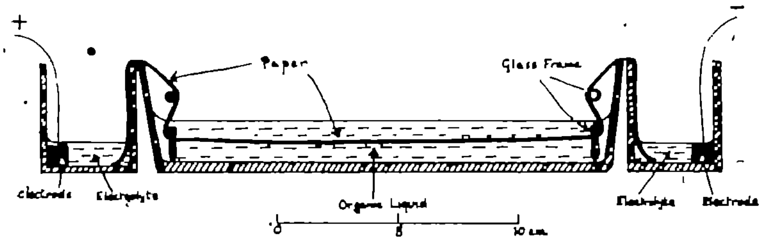
A Simple Paper Electrophoresis Apparatus

Electrophoresis and ionophoresis on paper are being widely used, and a number of different forms of apparatus for carrying out this technique have already been described. The purpose of this communication is to give further details of an apparatus already briefly described[1], which has been used for a considerable time with satisfactory results. While we do not claim that it is superior to other types of apparatus, it has the advantage of simplicity, results are reproducible, and the movement of a given substance varies linearly with time. The cross-section is shown in the accompanying diagram. The apparatus consists of a flat rectangular glass tray in which stands a closely fitting glass frame which carries the paper strip and rectangular 'Perspex' electrolyte boxes. The dimensions of the apparatus are not critical, but glass drip-trays from refrigerators are very convenient, the outside measurements being about 35 cm. × 20 cm. × 5 cm. The frame is constructed of two rectangles of glass rod, mounted one over the other, and separated from each other by



Cross-section of paper electrophoresis apparatus

about 1·5 cm. by means of sealed-on pieces of glass, or by pieces of cork at the corners. The frame stands on short legs to keep the paper away from the floor of the tray. Each electrode box has a hole drilled through the end about 1 cm. above the bottom. This enables electrolyte-levels in both boxes to be balanced prior to electrophoresis, and also permits old electrolyte to be run out and replaced by fresh, should this be desired.

The usual procedure is to soak the paper in electrolyte, remove excess liquid by blotting, and drape through the frame as shown in the diagram. The whole apparatus is mounted level, and the levels of electrolyte are not higher than that of the paper. The solution to be analysed is applied to the paper in the usual way[1,2]. An organic liquid is now poured into the tray, so that the paper is covered. Glass pieces are placed in the electrolyte boxes to keep the paper from contact with the electrodes, and the whole tray may be covered with a glass lid. At the end of the experiment the frame with the paper is removed and dried.

Voltage, current and other conditions are as already described[1]. It has not been usual to control the temperature, but if the heating effect is too high, the tray is stood in a larger tray carrying cooling water. The organic liquid acts as a cooler and prevents undesirable evaporation of electrolyte. Chlorobenzene has normally been used in the organic liquid, because its specific gravity is similar to that of wet paper, and so allows the strip to remain horizontal; this helps to prevent secondary flow of electrolyte.

For a voltage gradient of about 10 V./cm. and with Whatman No. 1 paper, 2–3 hr. is normally sufficient for substances of moderately high mobilities; but for slower-moving substances, for example, serum proteins, 4–5 hr. is required. The distance of migration and also of electroendosmosis will, of course, vary with the type of paper. This is shown in the accompanying table, which gives the migration of human serum albumin in borate buffer, *p*H 8·6 at 10·3 V./cm. and average temperature 20°. Electroendosmosis was measured by the movement of creatinine from the origin. Migration refers to the distance between albumin and creatinine. All the papers listed were found to be suitable for simple substances such as amino-acids and sugars, but some were not suitable for serum proteins, and these are indicated. The migration of other given substances on the different papers varies similarly to that of albumin.

MIGRATION OF HUMAN SERUM ALBUMIN AND ELECTROENDOSMOSIS (CM./HR.) ON VARIOUS WHATMAN PAPERS IN BORATE BUFFER, *p*H 8·6 AT 10·3 V./CM. AT 20°

Whatman No	Electroendosmosis	Migration of albumin
1	0·9	3·2
2	0·9	2·8
3	0·9	3·4

20	0·9	2·7
42	0·7	2·4
50	0·2	1·4*
52	0·7	2·1
54	0·8	2·4
542	0·5	1·6*

* Not measurable accurately. These papers are unsuitable for serum proteins.

It is often desirable to carry out chromatography after the electrical separation in a direction at right-angles to that of ionophoresis[1]. The dimensions of the frame limit the length of paper available for chromatography, but an extra length can be obtained by folding a sheet of paper which is too long, so that it can be draped through the frame. An additional advantage of the frame for chromatography is that it eliminates undesirable contamination of the paper by the hands.

The choice of paper will be influenced by speed of migration and electroendosmosis (see table). Other considerations may limit the choice further. Thus, for quantitative work, a higher-grade paper than No. 1 may be necessary (for example, No. 20), or where more material is to be handled, a thick paper such as No. 3. The latter has been used for the isolation of milligram quantities of carbohydrates after ionophoresis. For certain purposes the ratio of electroendosmosis to migration of a given substance should be small[2], and papers Nos. 4, 5 and 50 have this property. In addition, the chromatographic properties of the paper will have to be taken into consideration, where two-dimensional separations are to be carried out, in view of the limits set by the apparatus on the length of paper available for chromatography. As is well known, a given substance will move chromatographically at different speeds on different papers in a given solvent system. Movement is relatively fast on No. 4, and this paper is therefore not suitable for substances of high R_F value, unless a short period of development is employed. Movement on Nos. 1, 3 and 54 is similar, while on No. 20 it is somewhat slower, and on No. 42 slower still. The latter is suitable for substances of high R_F value, and it also has the advantage of a high wet strength.

One of us (W. M. S.) is in receipt of a grant from the Medical Research Council.

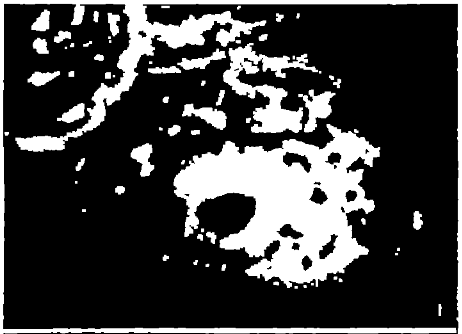
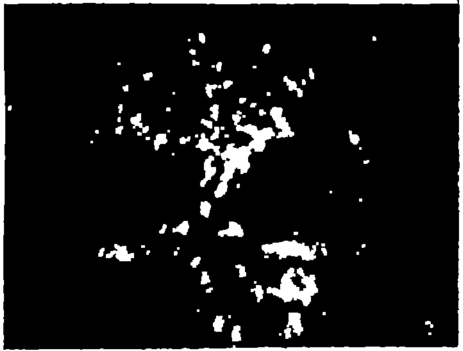
Pectinase Technique for Isolating Plant Cells

PLANT root meristems are a readily available source of mitotic cells which are ideal for cytological examination on account of their large size, high mitotic index and, in selected cases, small number of fairly large chromosomes. The root tip, in which the meristem is found, can be easily handled for experimental studies such as those on the uptake and distribution of phosphorus-32 relative to the mitotic





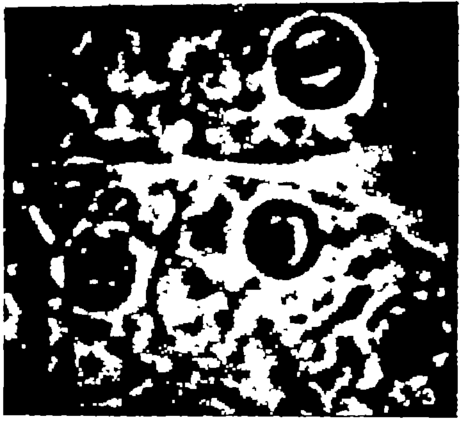


Fig. 1. A cell from the meristem of a lateral root of *V. faba* macerated in a living condition by pectinase. The cell was mounted in Tyrode solution diluted four times and photographed, unstained, in green light, final magnification, about 1,150. Note the dark nucleolus surrounded by a clear nuclear area and the presence of discrete granules in the cytoplasm

Fig. 2. Meristematic cells of a lateral root of *V. faba* treated with the pectinase and then with hot acetic-carmine. Photographed as for Fig. 1. Note the very dark nucleus and lack of discrete cytoplasmic particles

Fig. 3. Meristematic cells of a lateral root of *V. faba* treated for too long with the pectinase. Mounted in Tyrode solution and photographed as for Fig. 1. Note the dark nucleolus surrounded by a dark nuclear region; some nuclei show a light perinucleolar halo, probably due to the middle zone (ref. 3)

cycle[1]; or it can be used as a concentrated source of cell components such as nuclei[2] or cytoplasmic granules[3]. In general, the cells are studied after they have been fixed and subjected to some technique designed to render them clearly visible with a microscope. Such methods include embedding and sectioning, or treatment with hot acid, either normal hydrochloric or 45 per cent acetic, to weaken or remove the intercellular cement so that whole cells may be examined separately. Plant mitochondria, however, are extremely delicate and are destroyed by the fat solvents used in the process of embedding in paraffin wax and by the acids employed to remove the intercellular cement. The destruction of the mitochondria allows material which, in life, is localized on these bodies to diffuse about the cell, giving rise to serious artefacts. Thus the diffusion of ascorbic acid on to the chromosomes following the breakdown of the mitochondria has been reported[4], and it is likely that other acidic substances, if originally localized on cytoplasmic granules, could be similarly redistributed[5].

It is therefore desirable to be able to examine the living cells. A method for doing this was described[6] in 1949; the intercellular cement was removed by the action of a solution of a fungal pectinase. The technique required a period of treatment lasting three days, during which time it was difficult to keep the growth of micro-organisms to within suitable limits. The enzyme was obtained from *Penicillium digitatum* growth on bran. Different strains of the same fungus, and slight variations in the method of culture, were found to yield very different results when tested for maceration potency. It was clear that, while the technique was useful once the correct strain and culturing procedure were discovered, it could not obtain general acceptance until it was standardized with an enzyme preparation of constant composition which was universally obtainable.

Recently, the Nutritional Biochemicals Corporation of Ohio, U.S.A., has produced a commercial pectinase powder which is generally available and which has now been tested on root tips with good results. It is essential to use the pectinase in the presence of peptone and to restrict its time of action. Thus the root meristem cells of lateral roots of *Vicia faba* were treated for 50–60 min. with a 10 per cent solution, by weight, of this enzyme powder dissolved in a 1 per cent aqueous solution of peptone (bacteriological); the cells separated very readily when the root was gently teased with a needle. After this treatment many clearly outlined cytoplasmic granules were observed; the nuclei were optically homogeneous and contained well-defined nucleoli (Fig. 1). These cells were therefore very unlike root-tip cells viewed after the action of most standard techniques.

These living cells could be used to study the various artefacts produced by fixation. Thus, when alcohol was added to such cells, an obvious hardening or coagulation of the cytoplasm was observed. Treatment with hot 45 per cent acetic acid, or aceto-carmine, destroyed the cytoplasmic granules and made the nuclei appear dense and inhomogeneous (Fig. 2).

An artefact which in some ways resembled that observed after fixing with hot acetic-carmine was also seen after unduly long treatment with the enzyme solution. Thus, after two hours digestion, the large, clearly defined cytoplasmic granules had disappeared from all the meristematic cells and the nuclei were no longer optically homogeneous (Fig. 3).

The need for peptone and the importance of the length of treatment not exceeding the optimum suggest that the enzyme preparation may have a potential effect besides that of hydrolysing the intercellular cement. It may be that an impurity, such as a proteolytic enzyme, is present for which the peptone acts as a substrate so that only after this peptone is destroyed does the enzyme attack cell proteins.

The particular value of the present technique lies in the production, within one hour of removing the root apex from the seedling, of a 'squash' type of preparation in which the cells are apparently alive and show the detailed cytoplasmic organization and nuclear optical homogeneity usually lost on fixation. That such a cytological preparation can now be produced by the use of a commercial product which should not be very variable may allow the method to become of general application.

I wish to acknowledge the encouragement and advice given me by Prof. J. T. Randall and by Dr. Honor B. Fell, and to record my debt to Mrs. U. J. Horne for her help in this work. The investigation has been aided by a grant from the British Empire Cancer Campaign.

A New Pyrimidine Base from Bacteriophage Nucleic Acids

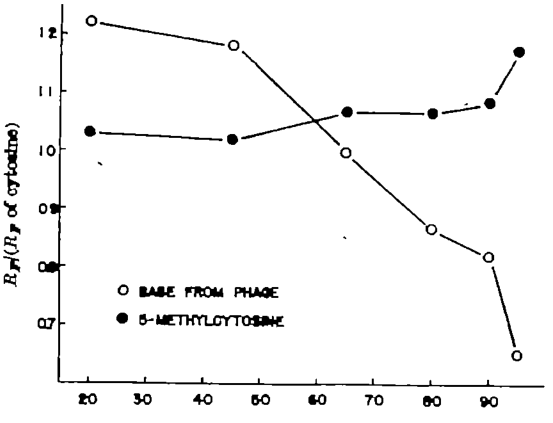
THE pyrimidine cytosine[1] and its deoxynucleotide[2] have been reported as constituents of the deoxyribonucleic acids of coliphages *T2* and *T6* respectively, but in another analysis of *T2*[3] no cytosine could be found. We have now resolved this discrepancy by isolation from *T*-even bacteriophages of a new pyrimidine base, identified as 5-hydroxymethylcytosine, which was previously mistaken for cytosine or missed. A nucleotide has now also been isolated which gives rise to this base on hydrolysis[4].

The nucleic acid bases liberated by hydrolysis of whole viruses or virus deoxyribonucleic acid were separated on paper chromatograms using isopropanol – water – hydrochloric acid[5] as the solvent. When formic acid (88 per cent at 175° C. for 30 min.) was used for hydrolysis, a substance was obtained having the same R_F value in this system as cytosine but a slightly different ultra-violet absorption spectrum. Perchloric acid, which gives good yields of the other nucleic acid bases, largely destroys this substance.

Its structure was suggested to us by its spectral and chromatographic characteristics. The ultra-violet absorption maxima were close to those of cytosine and 5-methylcytosine, having parallel shifts with change in *p*H :

	Wave-lengths of maxima, mμ		
	0·1 *N* hydrochloric acid	*p*H 7·4	0·1 *N* sodium hydroxide
Cytosine	275	267	280
5-Methylcytosine	283	274	287
Base from phage	279	269·5	283·5

The relative positions of cytosine and the new substance on chromatograms were independent of the *p*H of the solvent, suggesting similar ionizable groups. The effect of the water content of the solvent on R_F values, however, illustrated in the accompanying graph, showed the relatively hydrophilic nature of the new base.



By treatment with nitrous acid, the base was deaminated to a product which was related in spectral and chromatographic properties to uracil in a similar way as the parent substance was to cytosine.

These properties suggested 5-hydroxymethylcytosine as a possible structure. A specimen of the base, isolated by a combination of chromatographic and chemical procedures from a large preparation of $T6r^+$ bacteriophage (for which we are indebted to Dr. J. Spizizen, of Sharp and Dohme, Inc.), had an elementary composition compatible with this structure (analyses after drying *in vacuo* at room temperature : calc. for $C_5H_7O_2N_3.\frac{1}{2}H_2O$: C, 40·00 ; H, 5·37 ; found : C, 40·23 ; H, 5·35 per cent. Analyses after drying over phosphorus pentoxide at 100° C. : calc. for $C_5H_7O_2N_3$: N, 29·78 ; found : N, 29·33 per cent). A sample of 5-hydroxymethylcytosine, kindly synthesized for us by Dr. C. S. Miller, of Sharp and Dohme, Inc., had ultra-violet spectra and chromatographic behaviour identical with those of the natural substance. On heating, both natural and synthetic products decomposed without melting. We conclude that the base found in the *T*-even bacteriophages is 5-hydroxymethylcytosine.

By hydrolysis of whole viruses in formic acid, the following analyses were obtained :

	Moles per 100 moles total nucleotide				Base recovery / P
	Adenine	Thymine	Guanine	Hydroxymethylcytosine	
$T2r^+$	33·2	35·2	17·9	13·6	0·91
$T4r^+$	32·7	35·7	18·1	13·5	0·91
$T6r^+$	33·2	35·6	17·8	13·3	0·92

Neither cytosine, 5-methylcytosine, nor uracil could be detected. The values for 5-hydroxymethylcytosine are based on the extinction coefficient in 0·1 *N* hydrochloric acid (E = 9,700) ; they may be subject to correction for loss in hydrolysis. Repeated analyses of the *r* and r^+ mutants of *T2*, *T4* and *T6* phages did not indicate any significant differences in composition of the deoxyribonucleic acid.

Careful examination of deoxyribonucleic acid from thymus and from *E. coli* and whole dried *E. coli* failed to reveal any of the new pyrimidine in these materials, and it appears that it may be a unique virus constituent. This would then provide the first demonstration of a virus containing a chemical unit qualitatively different from those of its host.

These results will be reported more fully elsewhere. This work was done while one of us (S. S. C.) was in receipt of a grant from the Commonwealth Fund.

Cytoplasmic Polyhedral Virus Diseases

In the literature on the polyhedral virus diseases of insects, apart from the many nuclear polyhedroses of the fat-body (and cuticular tissues), only one case of a nuclear polyhedrosis of the gut and one cytoplasmic polyhedrosis of the fat-body have been described. Previously, no cytoplasmic polyhedrosis of the gut has been reported.

Several different cytoplasmic polyhedroses of the gut have now been found, and cross-infection to other species established with them. For example, cytoplasmic gut polyhedroses have been obtained on infecting *Vanessa io* larvæ with the polyhedra of *Rhypara purpurata*. The silkworm, *Bombyx mori*, develops similar polyhedroses on infection with the polyhedra of *R. purpurata*, *Arctia villica*, or the cytoplasmic gut polyhedra of *Sphinx ligustri*. Such polyhedroses have also been obtained in *Lymantria dispar* and *Aglais urticæ*, etc. It has been established that *villica* polyhedra give rise to a gut cytoplasmic polyhedrosis in their host species, *A. villica*. It is suspected, though not demonstrated, that this is also the case with *purpurata* virus in its natural host.

In all these cases, as with others, the cytoplasmic gut polyhedra have been found to be blue-staining with methylene blue even after only a very light heat treatment of gut smears. Nuclear polyhedra do not stain after such treatment. It has been previously established[1] that *villica* and *purpurata* polyhedra show an absence of membrane and virus rods when examined under the electron microscope after being treated with weak alkali. The same is true for *purpurata* polyhedra in the silkworm, and for the naturally occurring cytoplasmic gut polyhedrosis of the privet hawk (*S. ligustri*), the only ones of those mentioned so far examined[2]. All polyhedra of this type which have been examined showed the 'honey-comb' structure described by Smith and Wyckoff[1].

Provisionally, then, it can be suggested that two distinct types of polyhedral diseases exist. The polyhedra from nuclear polyhedroses do not stain with methylene blue, are readily soluble in alkali, and possess membranes. The polyhedra from cytoplasmic polyhedroses are readily stainable with methylene blue, are less readily soluble in alkali, are without membranes and leave a pitted 'honey-comb' structure after alkali treatment.

It is hoped that further research will establish the conditions favouring the development of one or other type of polyhedrosis, and whether under appropriate conditions a given polyhedral virus may give rise to a polyhedrosis in a different cytological and histological site from its original one.

Tainting of Tobacco by a Dichloropropene–Dichloropropane Soil Fumigant

One of the most serious pests of tobacco in Southern Rhodesia is the eelworm, *Heterodera marioni*. Control of this organism is effected by injecting the soil, by means of a plunger-type injector, with ethylene dibromide or a dichloropropene–dichloropropane mixture. During the 1951–52 growing season, it has been estimated that the latter fumigant has produced 'off-odours' in approximately five per cent of the tobacco crop. These odours first become apparent during the curing process, and persist through all subsequent stages of processing. Impurities in the fumigant mixture have been shown to be responsible for this tainting and have been isolated and characterized by the methods described below.

Green tobacco leaf was extracted twice successively with its own weight of ether, the combined extracts filtered and the ether distilled off. The residue was extracted with ethanol and chromatographed on aluminium oxide, using ethanol to develop the column. Spectrophotometric examination of the primary colourless eluate, collected before any pigment bands had passed through the column, showed that the tainted tobacco contained material absorbing in the deep ultra-violet that was not present in untainted leaf.

Fractionation of the primary eluate yielded two components, boiling at 69° (fraction *F*) and at 148° (fraction *X*). Comparison of the spectrophotometric absorption curves, boiling points, refractive indices and the melting points of the S-alkylisothiourea picrate derivatives (prepared according to Brown and Campbell[1]), together with mixed melting point determinations, have led to the identification of these two fractions with two of the components of the soil fumigant mixture, fraction *F* being tentatively identified as 2 : 2-dichloropropane and fraction *X* as 1 : 2 : 3-trichloropropane.

The concentration of the contaminating substances in the green tobacco leaf was found to be approximately nine parts per million. No such compounds could be isolated from untainted tobacco.

Paper chromatography of the leaf pigments, using methanol – hydrochloric acid – water (50 : 25 : 25) and ethanol – acetic acid (98 : 2) as the solvents, followed by elution of the separated pigment spots and their spectrophotometric examination, showed differences between tainted and normal leaf, several of the pigments from the tainted leaf exhibiting a shift of absorption maxima towards the red end of the spectrum.

It is thought that certain of the components of the soil fumigant mixture may be entering into the biogenesis of the leaf pigments, in place of their normal precursors.

The precise environmental conditions necessary to produce tainting and the effect of such tainting on the metabolism of the tobacco plant are, as yet, unknown. The problem is receiving further attention and the work will be published in more detail elsewhere.

A Growth Interaction between β-Indolylacetic Acid and Thiourea (Thiocarbamide)

In experiments designed to explain the activities of 3-indolylacetonitrile recently isolated by Jones, Henbest, Smith and Bentley[1] from brussels sprouts, Osborne[2] has shown evidence for synergism between this compound and heteroauxin (β-indolylacetic acid). The experiments were carried out on pea tissue, and the degree of curvature of split pea cotyledons measured in accordance with the standard Went pea curvature test[3].

Experiments carried out in this department show that thiourea also can interact synergistically with β-indolylacetic acid when both are applied simultaneously in aqueous solutions to germinating *Avena sativa* seedlings. The effects are shown in root-growth following a 48-hr. treatment and during subsequent shoot-growth following defoliation (100 plants per treatment).

The concentration of thiourea was of the same order as that tested by Amlong[4], namely, 2,000 mgm./litre, and that for β-indolylacetic acid of the order of 50 mgm./litre. Table 1 shows the effect on root-length following the 2-day treatment.

Table 1. Length of Longest Root (Mean Length (cm.))

Distilled water	2·6
Thiourea	2·1
β-Indolylacetic acid	0·8
Thiourea and β-indolylacetic acid	0·5

The inhibitory effects are greater in the case of treatment with β-indolylacetic acid than those with thiourea; but both treatments when compared with the controls treated with distilled water are statistically very significant. When both treatments are applied simultaneously the inhibition is greater than when the treatments are applied independently. This interaction proved to be highly significant, its variance ratio (*F*) having a probability less than 0·001.

Following this initial treatment, the seedlings were transferred to sand watered with a complete nutrient solution. Nine days after planting, the seedlings were defoliated, the region of defoliation being approximately 1 cm. above the growing-point. Table 2 shows the effect on shoot-height for the first month of the regeneration period.

Table 2. Mean Shoot Height per Treatment (cm.)

	Oct. 16	Oct. 23	Oct. 30	Nov. 6
Distilled water	1·6	2·6	4·6	5·4
Thiourea	1·6	3·9	4·6	6·3
β-Indolylacetic acid	1·5	2·9	4·6	5·5
Thiourea and β-indolylacetic acid	1·9	4·7	5·2	7·1

The interaction effects are statistically significant on October 16 and October 30, while on October 23 and November 6 both thiourea and β-indolylacetic acid, acting independently, produce differences which are also statistically significant. The increased rates of regeneration from both treatments are reflected in the dry-weight estimations of the shoots and leaves shown in Table 3, although the interaction effect fails to reach significance.

Table 3. Mean Dry-weight per Plant (gm.)

Distilled water	0·59
Thiourea	0·71
β-Indolylacetic acid	0·66
Thiourea and β-indolylacetic acid	0·80

Both thiourea and β-indolylacetic acid, acting independently, produce dry-weight increases which are significant.

Work of a fundamental nature similar to that carried out with auxins has not been attempted on a large scale with thiourea. It appears, however, from the work of Denny[5] that in the potato this substance stimulates a greater number of buds to develop from a single eye, and prevents the apical buds from inhibiting the growth of the basal buds. If it is assumed that this apical dominance is caused by auxin, then it appears that thiourea can destroy its action, or even prevent its formation. The above experiment, however, indicates that thiourea can react in a way different from this. When applied simultaneously with β-indolylacetic acid to germinating *Avena* seedlings, a greater inhibition of early root-growth, and a greater regeneration of shoot-growth after defoliation, is produced than that which is obtained when both substances act independently of each other. Thus, there is some evidence for synergism between these compounds in their effects on early growth of *Avena* seedlings.

Determination of Urinary Corticosteroids

A major difficulty in the estimation of urinary corticosteroids arises from their destruction under conditions necessary for the complete hydrolysis of steroid conjugates. Extraction of corticosteroids from non-hydrolysed or partly hydrolysed urine yields only a small fraction of the amount released by enzymatic hydrolysis with β-glucuronidase[1]. The existing procedures have been authoritatively discussed and their inadequacy pointed out by Marrian[2].

As reported elsewhere[3], 17-hydroxylated corticosteroids of types I, II and III (see table) yield 17-ketosteroids on oxidation with sodium bismuthate. The application of this finding to the oxidation *in situ* of urinary corticosteroids has now been studied with the object of converting steroids bearing any of the three side-chains I–III into a group of sub-

Substance added to urine (10 mgm./l.)	Type of side-chain	Increase of 17-keto-steroids (mgm./l.)	Increase of 17-ketogenic steroids (mgm./l.)	
		Found*	Found*	Expected
17α-Hydroxy-11-dehydro-corticosterone	 (I)	0·3	4 9	8 1†
17α : 20β : 21-Trihydroxy-pregn-4-en-3-one	 (II)	0 4	8·9	7·9†
3α : 17α · 20β-Trihydroxy-pregnan-11-one	 (III)	0 5	6·0	8·2†
3α : 17α-Di-hydroxy-pregnane-11 : 20-dione	 (IV)	2·3	0·4	6·4† 0‡
Dehydroepi-androsterone	(V)	9·3	0·3	0

* Colour equivalent after correction for non-specific absorption (ref. 8) in terms of mgm. dehydroepiandrosterone as standard; the figures represent averages of four to seven estimations.

† Assuming quantitative conversion to a 17-ketosteroid and colour equivalency with dehydroepiandrosterone.

‡ Assuming no oxidation occurred.

stances (17-ketosteroids) more resistant to acid hydrolysis and assayable by well-established methods. The difference between 17-ketosteroids found before and after oxidation of urine affords a measure of '17-ketogenic steroids' which represent an important group of corticosteroids. That certain urinary corticosteroids may be determined by their conversion into 17-ketosteroids has been previously shown by Talbot and Eitingon[4]. These workers used periodic acid as oxidizing agent, the oxidation being preceded by isolation of the steroid conjugates, their mild hydrolysis, and separation of the non-ketonic fraction from the hydrolysate.

The procedure for the direct oxidation of urine with sodium bismuthate is simple and rapid: 10 ml. urine and 10 ml. glacial acetic acid are mixed and shaken for ½ hr. with 2 gm. sodium bismuthate, the mixture is centrifuged and a suitable aliquot of the supernatant diluted with an equal volume of water; the subsequent hydrolysis, extraction and determination of 17-ketosteroids can be carried out by any of the numerous existing methods. In the present investigation the procedure of Drekter *et al.*[5] has been adopted for hydrolysis and extraction, and a modification[6] of the Callow–Zimmermann reaction[7] for the colorimetric estimation. The 17-ketosteroid content of untreated urine is estimated concurrently.

By the method outlined above, the urines of two normal males were found to contain, respectively, 7·0 and 7·6 mgm. of 17-ketogenic steroids in 24-hr. specimens. The value found for the urine of a rheumatic patient following administration of 300 mgm. cortisone acetate was 125 mgm. per 24 hr.; the latter urine, when adjusted to *p*H 1 and extracted with chloroform, yielded only 2·5 mgm. of formaldehydogenic steroids per 24 hr.

In a series of experiments the 17-ketosteroids and the 17-ketogenic steroids of a urine specimen were estimated before and after addition of various steroids. The results (see table) clearly show that steroids bearing the side-chains I–III significantly increase the estimated 17-ketogenic steroids, while their effect on the 17-ketosteroid values is negligible.

The amount of urinary corticosteroids estimated by the bismuthate method is of a much higher order than that estimated by the usual procedures, and is only comparable with the amount of formaldehydogenic steroids released by enzymatic hydrolysis. It should, however, be emphasized that determinations of formaldehydogenic, reducing and 17-ketogenic steroids estimate different, though overlapping, groups of corticosteroids[8].

The present method is well suited for routine estimations. A more detailed account of this work will be published elsewhere.

I am greatly indebted to Dr. H. F. West for his interest in this work. My thanks are also due to Mr. R. D. Stubbs for valuable technical assistance. Specimens of steroids were kindly provided by Messrs. British Schering, Ltd., and N.V. Organon (Oss).

Irradiation of Linear High Polymers

A VARIETY of polymers have been subjected to irradiation in the Harwell pile, and electrons from a Van de Graaff generator, the results being followed mainly by X-ray diffraction. The initial effect is to break down bonds, some ionic, the majority covalent. The radicals formed can react in a number of ways. In the presence of oxygen they can form low-molecular weight compounds and carboxyl end-groups; different end-groups and low-molecular weight compounds can be formed in the absence of oxygen; they can reform the original bonds; or they can recombine in other ways.

The proportions in which these reactions occur depend on three main factors:

(*a*) Presence or absence of air or other reacting medium. Two examples may be quoted to illustrate this. Many workers with the electron microscope have noticed that thin films or small particles of polymeric material are 'stabilized' by beams of moderate intensity, becoming more resistant to the effects of both heat and their normal solvents. In the process specimens often darken. In the present work, samples have been exposed to electrons in the presence of air, and quickly broken down. In vacuum, reactions between the free ends have resulted in the formation of covalent or dipolar bonds to produce a polymer of greater stability; while in air, interaction with oxygen has resulted in a loss of radicals as volatile compounds. It has been noted that, even after considerable breakdown, X-ray diffraction frequently gives the characteristic patterns of the original polymer; while in one instance—nucleic acid—a product which presented a black and charred appearance was analysed chemically and showed remarkably little evidence of drastic breakdown. The second example is that of polyethylene. On pile irradiation the surface rapidly becomes sticky, but polyethylene containing carbon black does not produce this oxidation reaction for several days, since oxygen reacts more readily with carbon.

(*b*) Intensity of irradiation. When allowance is made for the heating effect of the electron beams, differences between the effects of the pile and the Van de Graaff generator can be interpreted as differences of degree rather than of kind. Similarly, with a single type of irradiation, in certain instances, it appears that a different dose-rate can produce somewhat different effects.

(*c*) Chemical nature of the polymers. Effects noticed after irradiation, and the rate and type of breakdown, can to a large extent be correlated with chemical groups within the polymers and with the nature of the crystallites which are present, and the polymers can be classified accordingly. In general, the factors considered by Hill and Walker[1] in their work on the relation between polymer constitution and the ability to assume a polycrystalline form with adequate thermal stability apply in this case also. Polymers which on irradiation retain their strength the longest are those which are able to form a 'close-packed' type of crystallite—linear high polymers without side-chains—the crystallites being more resistant to breakdown by radiation than the non-crystalline regions.

When exposed in the presence of air, the non-crystalline regions in fibres of polyamides or polyethylene eventually become fluid, with the solid crystallites (as shown by sharp reflexions in X-ray diffraction patterns) remaining in the viscous medium. In the absence of air, the effect on the non-crystalline regions is different. In many instances an initial increase in strength has been reported[2]. It may be assumed that the free radicals recombine to form more stable groupings, possibly with bridges between one chain and another, and possibly with linkages of a different ionic character. Infra-red and thermal measurements will be necessary to estimate the relative importance of these. Almost certainly the formation of unsaturated rings is an important factor in preventing the rapid break-down that might be expected from the total energy received. Polystyrene is more resistant to irradiation than polyethylene[2], and polyethylene terephthalate than the aliphatic polyesters. Similarly, the purine and pyrimidine groups in the nucleic acids seem able to protect the sugar portion of the molecule. In the case of polyethylene terephthalate, with oxygen atoms in the main chains, further condensation would be difficult, and the polymer is observed to become brittle at quite an early stage.

With long-chain polymers containing aliphatic rings, diffraction results indicate that the crystalline regions break down almost as readily as the non-crystalline—the diffraction rings become diffuse before the specimens have lost their strength. However, physical properties such as solubilities and melting points are affected in a similar manner to other polymers. In this group are cotton-wool and the various cellulose derivatives, and also collagen.

Another group of compounds requiring mention are those containing atoms or radicals which are readily and permanently lost, as, for example, those attached by an ester link—loss of the acetate radical causes cellulose acetate to break down more rapidly than viscose.

Naturally occurring complex polymers are more difficult to classify than the synthetic polymers in that more than one effect may be operative. Thus the basic portion of the nucleic acid molecule contains both a stable ring system and the readily detachable amide groups. In this polymer it is possible to account for the decreased solubility which is observed without postulating carbon-containing bridges.

This work is to be published more fully elsewhere. I wish to thank the firms or individuals who have provided samples of polymers, Dr. P. Kent of the Biochemistry Department, Oxford, for analysis of nucleic acids, and the Director of the Atomic Energy Research Establishment for permission to publish this communication.

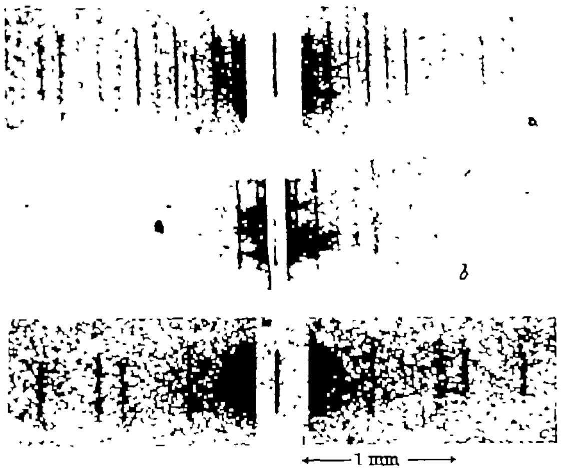
Small-Angle X-Ray Scattering

THE large lattice spacings occurring in such organic matter as fibres or crystalline viruses give rise to X-ray diffraction patterns with Bragg angles of minutes of arc rather than of degrees. The neighbourhood of the direct beam is, however, for a variety of reasons, easily obscured by scattered radiation and insufficient collimation, so that special measures such as very long film-specimen distances[1] or focusing crystal monochromators[2] have been used for obtaining satisfactory photographs. In particular, Furnas[3] has recently made an important contribution to the latter method.

We have now succeeded in obtaining, comparatively rapidly, clear photographs of small-angle patterns, by making use of a concave mirror in combination with a fine-focus X-ray tube[4,5]. A bent optical flat forms an image of the foreshortened X-ray focus ($5\,\mu \times 50\,\mu$) on a photographic film. The specimen is placed in the convergent beam in front of the film. Slits near the X-ray tube and near the specimen minimize unwanted radiation: the widths and positions of the slits are critical. Beyond about 20′ from the origin, the resolution is determined by the size of the focus and the specimen-to-film distance. Nearer the origin, stray radiation, mainly from the reflector, tends to obscure the pattern. The stray radiation depends on the dimensions of the components of the camera. A reduction in the width of this radiation is accompanied by a decrease in the intensity of the main beam. The effect of air scattering and incoherent scattering from the specimen is negligible, because the reflector is set near the critical angle of the characteristic radiation employed and thus hard radiation is suppressed.

The photographs shown herewith are produced with copper *K* radiation and a camera with mirror 4 cm. long, focus-to-film distance 30 cm. and specimen-to-film distance 5 cm. With this camera a spacing of 350 A. can normally be detected (Fig. *a*), the first



Enlargements of low-angle X-ray diffraction photographs. (*a*) Collagen from kangaroo tail tendon, 8 hr. exposure at 50 kV., 450 μamp The repeat distance is 640 A.; the second order (17′ deflexion) is clearly visible. (*b*) Collagen from stained rat tail, 30 min. exposure at 50 kV., 450 μA. The first order (8·5′ deflexion) is visible and corresponds to a spacing of 640 A. (*c*) Tobacco mosaic virus gel, 8 hr. exposure at 50 kV., 450 μamp. The lines nearest to the origin (41′ deflexion) correspond to a spacing of 130 A

few orders appearing within 30 min. With favourable specimens such as collagen stained with phosphotungstic acid, the range of visibility goes up to twice this figure, because the exposure times are short, the first few orders appearing within 5 min. Fig. *b* is not fully representative, as it has been obtained with the width of the slit near the specimen below its optimum value. This increases the first-order visibility somewhat and the exposure-time by about a factor 3.

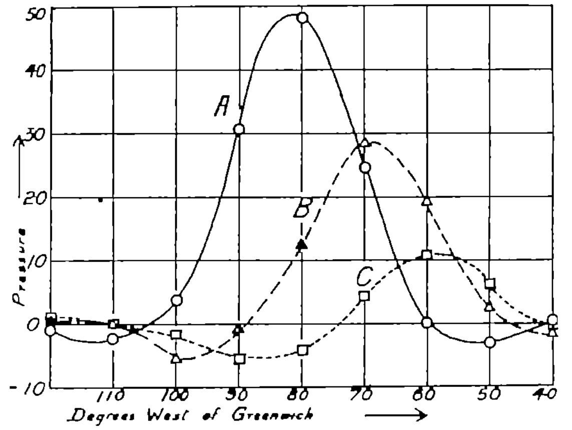
Behaviour of Atmospheric Pressure Systems

A method for studying the behaviour of atmospheric pressure systems has lately been developed at the local weather bureau at Pretoria. The general method, which can be applied in a number of different ways, can best be explained by a concrete example.

The departures (at a fixed hour) of daily pressure from the appropriate means were tabulated for 10-deg. grid points and expressed as percentages of the respective standard deviations. A grid point *P*, at 80° W., 50° N., was selected, and whenever the departure exceeded the standard deviation and formed a point of inflexion, the departure being greater than on the day before and on the day after, the date was written down. This occurred on 380 days during a period of ten years, 1929–38. The mean pressure for these 380 days was computed at *P* and at a large number of neighbouring grid points. The resulting mean isobars reveal an extremely simple pattern, since at all points sufficiently remote from *P*, the mean departure of pressure is practically zero.

The behaviour of this simplified isobaric pattern with the passage of time can now be readily studied. If one day be added to all the listed dates and the average pressure found for the new set of 380 dates, we obtain a chart of the mean isobars 24 hr. later.

In order further to simplify the picture of what actually happens, the pressures are shown graphically only for the 50th parallel north. Curve *A* was drawn to fit the original pressures as computed and shown in the accompanying figure. Curves *B* and *C* represent the distribution after one and two days respectively, the units of pressure used being quite arbitrary.



As one would expect, the isobaric pattern moves from west to east due to the prevailing westerlies In this case careful calculation indicates a displacement of 10·7 deg. or 413 nautical miles in 24 hr., equivalent to a speed of 17·2 knots, in close agreement with the known rate of travel of pressure systems.

The curves presented here show several other features, only one of which need be discussed at the moment. When the temperature distribution curves in a conducting rod, resulting from an instantaneous point source of heat, are graphically represented after fixed intervals of time, they show a striking similarity with curves *A*, *B* and *C*, except that the latter are displaced eastwards with the passage of time. It would therefore appear to be quite legitimate to introduce the concept of the 'diffusion of atmospheric pressure', and it should not be impossible to derive the laws of pressure diffusion even though they are bound to be appreciably more complicated than the analogous law of diffusion of heat. If these laws are reasonably well known, they could be applied to determine to a first approximation to-morrow's pressure at any point on the basis of to-day's pressure distribution. The preparation of prebaratic charts, as currently drawn at most forecasting centres, should thus be facilitated.

Research on the lines indicated is being continued at Pretoria and the results will be published in due course.

Apparent Absence of Low-Energy Primary Cosmic Radiation

The form of the energy spectrum of primary cosmic rays is still uncertain at the low-energy end. The work of Carmichael and Dymond[1] and of Bowen, Millikan and Neher[2] suggested that there was a lower limit at about 2,000 MeV., but this has not been confirmed by Pomerantz[3], who has come to the conclusion that the spectrum continues down to low energies. The matter is of importance owing to its cosmological implications. If the existence of a cut-off in the spectrum be established, some mechanism must be found either for removing the slower particles as they travel through space, or for their initial acceleration with a sharp low-energy limit. The suggestion of Jánossy that a solar magnetic dipole field might be responsible is not now supported by the astronomical evidence.

In a recent communication, Van Allen and Singer[4] have reaffirmed the existence of a lower limit in the energy spectrum, placing it at about 500 MeV. They have compared the vertical intensity of the radiation above the atmosphere, as measured in rockets at geomagnetic latitude 58°, with that determined by Pomerantz in balloon flights at 69°. The equality of the two intensities thus found leads to the conclusion that there are no primary protons in the range 130–560 MeV. It is reasonable to assume also that there are no protons below 130 MeV.

Some doubt must always arise about results drawn from comparisons of absolute intensities measured by different counter systems, owing to the difficulty of determining accurately the absolute flux from the observed counting rates and counter dimensions. But Pomerantz and McClure[5] have recently published some observations made with identical counter telescopes at 52° and 69°, so that the difficulty of comparison does not arise. They find that the hard component increases by a factor of about 1·4 near the top of the atmosphere between these two latitudes. This observation can be interpreted as showing a sharp cut-off in the energy spectrum. This spectrum has been reasonably well established in the region of higher energies by measurements at lower latitudes[1]. Using this and assuming the usual $\cos^4 \lambda$ relation between minimum particle momentum in the vertical direction and geomagnetic latitude λ, we can calculate the expected latitude farther north. We find that the intensity should rise by a factor 1·35 between 52° and 56°. As this is close to the factor found by Pomerantz and McClure between 52° and 69°, we conclude that the intensity must remain constant above about 56°, in approximate agreement with the statement of Van Allen and Singer. The argument is unaffected by the fact that Pomerantz and McClure have made their measurements on the hard component only, as the minimum proton energy required to penetrate the 7·5 cm. of lead absorber in their counter telescope is 260 MeV., which is well below the cut-off energy of the primary spectrum which their observations reveal.

The precise energy at which cut-off occurs must await more extended observations, particularly in the interesting region between 50° and 60°. One difficulty in fixing this energy-limit arises from the geomagnetic field itself. It is usual to calculate geomagnetic latitudes from geographical position by assuming that the field is that of a centred dipole, with axis pole at 78·5° N., 69° W. That this assumption is insufficiently accurate is shown by the existence of the longitude effect. A better approximation is given by an eccentric dipole, with axis cutting the earth's surface at 80·1° N., 82·7° W. For some stations the difference in geomagnetic latitude is not trivial, so the cut-off momentum, which varies as the fourth power of λ, is quite sensitive to the assumed position of the pole. For Edinburgh, for example, the minimum proton energy is 460 or 730 MeV., depending on the approximation used. A further element of doubt is introduced by our ignorance of how the dipole field behaves in relation to the known secular magnetic variations. It has been calculated only for the epoch 1922. More exact information on the terrestrial dipole field is required before cosmic ray data on energy limits can be accurately interpreted.

Cross-polarization of the Radar Melting-Band

When plane-polarized radiation is scattered by meteorological precipitation particles other than spheres, a component of the back-scattered energy is polarized at right-angles to the plane of polarization of the incident wave. This component will be referred to as the 'cross-polarized' component in this communication. Recent observations at Cambridge and Malvern have shown that the melting particles found just below the freezing-level, which give rise to the well-known radar 'melting-band'[1], produce back-scattered radiation with a greater cross-polarized component than that given by the rain below and the snow above the freezing-level. These observations have been made using separate aerials for transmission and reception, by comparing the echo received when the aerials have their planes of polarization parallel with that received when the plane of polarization for reception is at right-angles to that for transmission.

A wave-length of 3·2 cm. was used at the Cavendish Laboratory and a wave-length in the 8-mm. band was used at the Telecommunications Research Establishment, Malvern. Let I_1 denote the echo intensity measured with parallel planes of polarization and I_2 that measured with crossed planes of polarization; then Table 1 summarizes values of the ratio I_1/I_2 measured on several occasions at the two wave-lengths. Measurements were made of the intensity not only of the melting band echo, but also of the echoes from the rain below the freezing-level and the snow above.

Table 1 RATIOS OF THE INTENSITIES OF THE MAIN COMPONENT TO THE CROSS-POLARIZED COMPONENT

Wave-length (cm.)	I_1/I_2		
	Rain	Melting region	Snow
0·8	15±1 db.	7±1 db.	12±2 db.
3·2	21·8±0·4 db.	16·9±0·3 db	19·9±0·6 db.

When the transmitting and receiving planes of polarization are crossed, the maximum echo intensity is received from the same range as when the planes are parallel.

Because the echoes from the snow above the freezing-level are weak, there is some uncertainty about the figures in the last column in Table 1.

The ratio I_1/I_2 in Table 1 for rain is not reliable, but probably indicates that the aerial system used introduced a cross-polarized component almost as great as that measured for rain. This suggestion is supported by direct measurements made at Malvern of the characteristics of the 8-mm. aerial.

The results might be explained in two ways. First, the cross-polarized component might be introduced by multiple scattering, in which the energy arriving back at the receiver has undergone scattering by more than one precipitation particle. Although the ratio of secondary to primary scattered field should be greater by about 12 db. for the melting-band echo than for the rain echo, because of the greater concentration of particles in the melting region, preliminary calculations for a wave-length of 8 mm. have indicated that the secondary scattered field for rain of the appropriate precipitation-rate will be about 60 db. less intense than the primary scattered field, while the tertiary scattering will be even weaker. Thus the secondary scattered field can give only a negligible contribution to the cross-polarized component measured in the echo.

Secondly, the cross-polarized component might be directly introduced by the scattering particles. There are three types of particle to be considered: raindrops, dry snowflakes, and the wet snowflakes found in the melting region. Raindrops, which can be considered as spheres, introduce no cross-polarized component[2]. The cross-polarization introduced by non-spherical particles has not been worked out in detail, though Cabannes[3] has investigated Rayleigh scattering (in which only the induced electric dipole is taken into account) by randomly orientated isotropic ellipsoids, the principal polarizabilities of which will usually be unequal. Maxwell[4] gives an expression for the three principal polarizabilities of an ellipsoid, and Stoner[5] has used this expression to compute 'demagnetization factors' for ellipsoids of revolution. From the work of Cabannes and Stoner, it is simple to compute the cross-polarization that would be introduced by ellipsoids of revolution. The cross-polarization increases with the dielectric constant of the particle, so that, if snowflakes be regarded as spheroids, the theory predicts a greater cross-polarized component from the wet snowflakes (of dielectric constant 70) in the melting region than from the dry snowflakes (of dielectric constant 3) above. Table 2 shows some values of I_1/I_2 for several values of m, the ratio of the lengths of the polar and equatorial axes. It is hoped to extend these calculations to include scattering by spheroids which, like falling snowflakes, are not randomly orientated.

Table 2. PREDICTED RATIOS OF THE MAIN COMPONENT TO THE CROSS-POLARIZED COMPONENT

m	I_1/I_2 (melting snow)	I_1/I_2 (dry snow)
0·10	10·2 db.	14·7 db.
0·33	14·6 db.	18·2 db
0·67	18·5 db.	25·8 db.
1·00	∞ db.	∞ db.
1·50	16·0 db.	24·6 db.
3·00	9·0 db.	18·2 db.
10·0	5·8 db	15·2 db

If this explanation be correct, it follows that the particles in the melting-region must preserve their non-spherical shape until melting is almost completed.

These observations of a strong cross-polarized component in the melting-band have considerable meteorological interest in that they indicate a method of detecting the presence and, perhaps, determining the shape, of small quantities of ice in rain-clouds. On occasions, a melting-band which could not be detected by a conventional radar has been revealed by using one of the radars described here, in which the plane of polarization for reception was perpendicular to that for transmission.

Acknowledgment is made by one of us (N. P. R.) to the Chief Scientist, Ministry of Supply, for permission to publish this communication, and by the other (I. C. B.) to the Master and Fellows of Trinity College for the award of a Twisden Studentship.

Delayed Brittle Fracture of Alloy Steel at Low Stress Levels

THE recent publication by Petch and Stables[1] dealing with the delayed fracture of metals under static load has been read with interest. Work of a similar nature, to investigate the liability of an alloy steel to crack in the heat-affected zone when it is metal-arc welded under certain conditions, has been in progress in the laboratories of the British Welding Research Association since December 1951.

The effects which occur in the heat-affected zone of a weld have been imitated, so far as possible, in mechanical test pieces. The specimens were tubular in form with screwed ends and a gauge-length of 0·2 in. Each specimen was notched circumferentially to a depth of 0·019 in. The notch had a 45° included angle and a 0·005-in. root radius. The area of cross-section under the notch was 1/50 sq. in. and the wall thickness was 0·039 in.

The treatment of the specimens comprised supersaturation with hydrogen, rapid heating to a peak temperature in the region of 1,250° C. followed by cooling at selected welding-rates. The specimens were then examined by each of the following tests: (*a*) impact tensile test, at a velocity of impact of 22 ft. per sec.; (*b*) slow tensile test, at a strain-rate of 0·1 in. per min.; (*c*) dead-load tensile test, giving rupture after a period varying from 1 min. to several hours.

Some results of these tests on a low-alloy steel containing 0·19 per cent carbon, 1·3 per cent manganese and 0·25 per cent molybdenum are given in

Condition of specimen	Impact tensile test: energy to fracture (ft. lb.)	Slow tensile test: U.T.S. (tons per sq. in.)	Dead-load tensile test. stress just producing rupture (over notched area) (tons per sq. in.)
1. As-rolled	4·1	49·5	47
2. Untreated, high cooling-rate simulated	8·1	111	93
3. Hydrogen-treated, high cooling-rate simulated	6·7	63	27
4. Hydrogen-treated, low cooling-rate simulated	4·7	64	57

the accompanying table. The results show the increased influence of hydrogen on the strength as the rate of straining is decreased; Petch and Stables observed a corresponding effect on ductility. The results are mainly for duplicate tests.

These results give a better understanding of the factors affecting the formation of brittle hard-zone cracks during the welding of this type of alloy steel. We have observed that cracks occur in welding this steel only when relatively high hydrogen contents and high cooling-rates occur in the weld zone together[2], that is, condition 3 in the table. This observation is based on tests made on a structure, in addition to laboratory tests.

The impact tensile test results do not show any deterioration in properties in any of the conditions 2, 3 or 4 when compared with the as-rolled plate material (condition 1). Therefore, formation of hard-zone cracks is not related to this property of the steel. In this rapid test there is probably no time for the diffusion of hydrogen to take place during testing and so to cause embrittlement.

The slow tensile test is also quite rapid, and the time available for the diffusion of hydrogen is limited. The strength of the material is, however, reduced considerably by the presence of hydrogen, as shown by a comparison of conditions 2 and 3. Similar tests with specimen of condition 3 on un-notched specimens gave a value of reduction in area of only 5 per cent, which indicates that considerable embrittlement is produced in the steel in this condition. In spite of this reduction in ductility, the slow-tensile strength in condition 3 is greater than that of the as-rolled material, and, therefore, this property also is not a direct index of the tendency to form hard-zone cracks.

The dead-load test gives a good indication of the liability to crack formation, since brittle cracks might be expected only when the minimum rupture stress of the heat-affected zone falls below that of the background plate material, namely, 47 tons per sq. in., which occurs in condition 3, combined also with the low reduction of area of 5 per cent mentioned above. With this condition, the fracture produced is completely brittle, and there is ample time for diffusion of hydrogen to occur during the test.

Edmond About and the Technique of Freezing and Drying Tissues

In *Nature* of September 27, p. 547, Dr. L. G. E. Bell asks for the source of Edmond About's information on the technique of the preservation of tissues described in 1862 in About's scientific novel "L'homme à l'oreille cassée". The material that I am actually collecting for the purpose of writing the history, which covers nearly a century, of the Marine Laboratory at Concarneau, enables me, I believe, to reply.

Coste created this Laboratory in 1858 for the purpose of "la mise en culture des mers". In 1873, after his death, the work was continued by Charles Robin and Georges Pouchet, interesting scientific personalities who had strong links with the literary world.

Robin (1821–85) was professor of histology in the Faculty of Medicine in Paris, holding a chair created for him; he was a member of the Institut de France and of the Senate. The Goncourts have described him as "au cerveau tout à la fois nuageux et plein d'éclairs, et à la langue brouillée". He had been taken by Littré to the lectures of August Comte, had become a positivist and published with Littré the "Dictionnaire de Médecine", which ran to many editions. Robin carried out a considerable amount of work, chiefly in anatomy and cellular physiology. He had a number of followers, one of the more celebrated of whom was without doubt Clemenceau, who dedicated his thesis to him. His influence made its mark on a number of writers, as did that of Pouchet, of whom it was said that he was the scientific consultant of one literary generation.

Robin practised medicine at Mérimée; he documented Michelet's "L'oiseau", "L'insecte" and "La mer"; he was the friend of Taine and Sainte-Beuve, who like him had studied medicine at first. During these years, Sainte-Beuve, Robin and Pouchet met each week at Princess Mathilde's house, and then dined at Magny's, where they were frequently joined by Flaubert (he stayed with Pouchet one summer at the Concarneau Laboratory), the brothers Goncourt, Viollet-le-Duc, Théophile Gautier, Berthelot, Renan and many others. The "Journal" of the Goncourts is strewn with table-talk of Robin.

Among the convivial figures was Edmond About, who could thus have heard about topics which Robin was familiar with, such as the desiccation and the revival of the guinea worm which Robin studied in 1855, or the echo of discussions on the Tardigrades between Doyère and Pouchet's father, who was a partisan of spontaneous generation and against Pasteur. Further, the source of About's information is apparent: one of the principal characters of "L'homme à l'oreille cassée" is Dr. Nibor, an anagram of Robin, and they resembled each other. Also, the novel did not please Clemenceau, who criticized it. Another novel by About, "Le nez d'un notaire", is one story of van Helmont as recounted by Robin.

Further information can be found from the following works: G. Pouchet, "Charles Robin, sa vie et son œuvre", p. 195 (Paris, 1887); V. Genty, "Un grand biologiste, Charles Robin; sa vie, ses amitiés philosophiques et littéraires" (Lyon, 1931); and, concerning Pouchet, in C. Chassé, "Le biologiste consultant d'une génération littéraire: Georges Pouchet (1833–1894)", *La Grande Revue*, 28, 295 (1924).

Laboratoire maritime du Collège de France,
Concarneau, Finistère.

FORTHCOMING EVENTS

Monday, December 22

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Eric Shipton: "Expedition to Cho-Oyu".

Saturday, December 27

Royal Institution (at 21 Albemarle Street, London, W.1), at 3 p.m.—Dr. F. Sherwood Taylor: "How Science has Grown". (Christmas Lectures adapted to a Juvenile Auditory.) (Further Lectures on December 30, January 1, 3, 6 and 8.)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Experimental Officers and Assistant Experimental Officers in various Government Departments, for posts in (*a*) mathematical and physical sciences, (*b*) chemistry and metallurgy, (*c*) biological sciences (biological research and infestation control), (*d*) engineering subjects, and (*e*) miscellaneous, including geology, library and technical information services—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.94–95/52 (December 31).

Lecturer in Clinical Pathology at the University Veterinary Laboratories, Langford—The Registrar and Secretary, The University, Bristol (December 31).

Senior Scientific Officers (Ref. S.53/52) and Scientific Officers (Ref. S.52/52 and S.128/52) (Patent Examiner and Patent Officer classes) in various Government Departments covering a wide range of scientific research and development in most of the major fields of fundamental and applied science—The Civil Service Commission, Scientific Officer Branch, Trinidad House, Old Burlington Street, London, W.1, quoting the appropriate Ref. No. (December 31).

Lecturer in the Department of Geology (knowledge of petrology and mineralogy is essential)—The Registrar, Queen Mary College, Mile End Road, London, E.1 (January 1).

Senior Lecturer or Lecturer in Physics at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 15 Victoria Street, London, S.W.1 (January 1).

Principal Scientific Officer, Senior Scientific Officer, Scientific Officer (Grade 3), Scientific Officer (Grade 1), Senior Experimental Officer, Experimental Officers (Grade 3), and Experimental Officers (Grade 1), for research, design and development on electronic defence problems, at the Electronics Research Laboratory, Salisbury, Australia—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (January 3).

Lecturer in Chemistry (with an interest in inorganic chemistry)—The Secretary, The University, Aberdeen (January 5).

Research Officer (Mycologist) (with university honours degree in science or agricultural science, including research experience, or equivalent qualifications) in the Division of Food Preservation and Transport, Homebush, New South Wales, to undertake investigations on problems of mould wastage in stored fruits—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 (January 9).

Civil Engineers (40) and Mechanical and Electrical Engineers (30) in connexion with the Bhakra Nangal Project—The Chief Engineer, Irrigation Works Punjab, Ellerslie, Simla 2, India, endorsed 'Specialist Officers' (January 15).

Science Graduate as Assistant Librarian—The Librarian, University College, Gower Street, London, W.C.1 (January 15).

Readership in Physiology at St. Bartholomew's Hospital Medical College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 22).

Readership in Anatomy at St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 26).

Readership in Geography at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 29).

Senior Lecturer in Soil Conservation and Irrigation in the Department of Agriculture, University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (January 31).

Chair of Geography—The Secretary of University Court, The University, Glasgow (February 14).

Senior Lecturer in Pure Mathematics at the University of Otago, Dunedin—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (February 15).

Assistant Lecturer in Bacteriology (qualified to specialize in Dairy Bacteriology) in the Department of Agricultural Sciences at the School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

Lecturer in Metallurgy (a degree or equivalent qualification in metallurgy is essential)—The Principal, Technical College, Cole Street, Scunthorpe, Lincs.

Physicists (with a first- or second-class honours degree or equivalent in physics) at the Ministry of Supply Establishment, Aldermaston: Principal Scientific Officer to supervise a group engaged on research and development work in relation to problems involving radioactive materials (Ref. A.324/52A), Senior Scientific Officer or Scientific Officer to take charge of a group and for research on application of a 3 M.E.V. linear accelerator (Ref. A.325/52A), and Scientific Officers to work with a group engaged in research on certain aspects of physical properties of radioactive materials (Ref. A.326/52A)—The Ministry of Labour and National Service, Technica and Scientific Register (K), Almack House, 26 King Street, London S.W.1, quoting the appropriate Ref. No.

Research Engineer (with honours degree in engineering o science)—The Secretary, British Internal Combustion Engine Researc Association, 111–112 Buckingham Avenue, Slough, Bucks.

Science Graduates and Rubber Technologists (preferably wit experience of rubber technology in either a laboratory or factory) a the Rubber Research Institute of Malaya, Kuala Lumpur—Th Secretary, London Advisory Committee for Rubber Research (Ceylo and Malaya), Imperial Institute, South Kensington, London, S.W.7

Scientific Officers (with a first- or second-class honours degre in physics with mathematics, or equivalent, and a leaning toward experimental rather than theoretical work) in the Radio Divisio Royal Aircraft Establishment, Farnborough, for investigations in th field of radio frequency measurement, especially at V.H.F. and centi metric frequencies—The Ministry of Labour and National Service Technical and Scientific Register (K), Almack House, 26 King Street London, S.W.1, quoting A.314/52A.

SHORTAGE OF SCHOO[illegible] TEACHERS

THE Barlow Committee asked the uni[illegible] Great Britain to double their pre-war [illegible] science graduates by 1955, and they had almost [illegible] so by 1952. But in spite of this, there is a grave shortage of science teachers in schools and a serious decline in the academic quality of those presenting themselves, suggesting that the foundations of the educational structure for training science graduates are unsound.

The Incorporated Association of Head Masters, consisting of the heads of all boys' or mixed public and grammar schools in England and Wales, asked its members for particulars of their science staffs in July 1950. It received replies from four-fifths of their schools, employing 3,065 science teachers. In these schools, 193 science posts were unfilled; in 48 schools a science subject had been dropped from the curriculum because it had been impossible to find anyone to teach it. Perhaps the shortage of science teachers might have been at its worst in 1950, because 'sixth forms' were already twice their 1939 size, while the additional number of teachers expected from the increase in numbers at the universities had not yet reached the schools. But the experience of head masters in the next two years suggested that the position was getting worse rather than better; so, in July 1952, the Joint Four, which is the name given to the association of heads and assistants of public and grammar schools in England and Wales, undertook another survey. Three-quarters of the schools replied; 49 posts in boys' and mixed schools and 116 in girls' schools were unfilled. Again, 145 science posts for men and 128 for women vacant in September 1952 were advertised between May 30 and July 25. It is unlikely that any of these vacancies has been filled; no teacher already in a post could apply, as notice must be given by May 31 to be free to go to a new school in September; and the few scientists at the university seeking their first teaching posts in September would have been engaged before the previous June. Thus some two hundred and fifty posts for science teachers in Britain will remain vacant for the whole of the present school year; for if any of the above September vacancies are filled in January 1953, it will only be by creating a vacancy in another school. So some 190 vacant posts in boys' and mixed schools in 1950 has become between 50 and 140 in 1952. The shortage of science teachers in these schools persists, and it is pertinent to add that it leads to a continuous movement of science staff from one school to a better post in another. Nowadays, it is common for five out of a science staff of six to leave a school in the course of five years, so that even when no post is unfilled there is little continuity in the science teaching in the school. The position in girls' schools in Britain is even more serious, for 120 posts remain unfilled, which is one-fifth of their vacancies. Also it is well-nigh impossible to get teachers for girls' schools qualified to teach the 'science sixth', and university departments of [illegible] receiving women science students [illegible] ainments. So the cessation of the [illegible] men science graduates is within sight, [illegible] schools will shortly be unable to train [illegible] the standard for admission to the science [illegible] the universities.

[illegible] ere has also been a decline in the qualifications of science teachers since 1939. Here it should be pointed out that high scientific attainment at the university does not necessarily imply ability as a teacher. The survey conducted by the Incorporated Association of Head Masters in 1950 claimed that one-fifth of the science teachers in boys' and mixed schools in Britain were not properly qualified for the work they were doing. In 1952 the survey made by the Joint Four, when the increased size of the universities had had time to increase the supply of science teachers, reveals a similar state of affairs: only 39 per cent of the science teachers taking up their first posts in September 1952 had first- or second-class honours degrees, compared with an average of 55 per cent in the schools before the War. In 1949, the Cambridge University Appointments Board was told of 400 vacant science posts. Before the War it would have filled 100; probably another 50 would be filled by Oxford and the remaining 250 by the other universities of Britain. But in 1949 Cambridge could fill only 59 of these science posts, and in 1950 only 11 Oxford science graduates out of a possible 213 took up teaching; none of them had a first-class honours degree and only three had seconds. It is clear that the schools are not getting back as teachers anything like as many of the abler boys and girls as they did before the War—and certainly not a fair share of them, if the schools are to do the work the nation expects of them.

This decline in scientific quality of science teachers is confirmed by the facts at individual schools. One leading State grammar school, with a distinguished list of academic successes making its vacancies very attractive, has had five chief science masters since 1942 The same school lost its second chemistry master, who went to another well-known grammar school as chief science master. His post was advertised three times; there was no applicant. The vacancy was temporarily filled by a pass-graduate who was giving up industrial chemistry at the age of forty-five and taking up teaching; after three years he is still holding the post. Of course, if good results are being obtained, then the authorities must congratulate themselves on having a good teacher—pass degree notwithstanding. In 1950 a well-known grammar school in a large city in the south of England had four first-class honours graduates on its science staff; in 1952 there is only one left, the chief science master, who is receiving a special responsibility allowance. These facts illustrate the drop in academic standing of science teachers in Britain since 1939. This decline in quality might well lead to a drop in the level of attainment of science specialists in the schools, so that fewer will gain admission to the universities. The universities in turn will produce fewer science graduates, and fewer science teachers than ever will enter the schools. We shall then have slipped back to the position which existed in 1900, when most science graduates started their science at the university, and the fruits of forty-five years hard work, by which the schools laid the foundations and the universities concentrated on the advanced work, will have been thrown away One further fact underlines the precarious condition of school science. Too great a proportion of the good science teachers are more than fifty years old, so that the schools will lose most of them in the next ten to fifteen years.

What are the causes of this deplorable state of affairs? First, since the War we have tried to enlarge the universities, the Scientific Civil Service, the industrial research laboratories, the medical services, and the schools. Is it not possible, and even likely, that we are not producing, and never can produce, enough scientists to meet all these needs? Secondly, the salary of science teachers is too low. Before the War, a science teacher got £480 per annum—about the same as a university lecturer (£500 per annum) and about the same as he could get in the Scientific Civil Service or industry. To-day a science teacher gets £706 per annum, while a university lecturer gets £1,100 per annum and family allowances; and the Scientific Civil Service and industry are on similar scales. The science teacher's salary has not increased at the same rate as salaries in other occupations open to him. Before the War, the salaries of science teachers were determined by a separate Grammar School Burnham Committee, where the particular interests of all grammar school teachers received proper consideration. This separate Committee was abolished by the 1944 Education Act, and now the salaries of teachers in all types of school—nursery, primary, secondary modern, secondary technical and grammar—are settled by one Burnham Committee, in which grammar school teachers are in a minority. Their interests have received insufficient attention, because the majority of teachers on the Burnham Committee have failed to appreciate the importance of the grammar school in the national system of education. Finally, before the 1944 Education Act, there were two types of school, namely, elementary schools and grammar schools, and they were administered quite differently. Now all schools are administered in the same way; and unfortunately most local education authorities are administering all schools as they formerly administered elementary schools, in which the seat of authority was at the education office. Head masters and assistant masters feel that they have no longer the authority and freedom to do their work efficiently. They resent this loss of freedom, which is against the interests of their pupils and produces a sense of frustration, and is causing teachers to leave State grammar schools for independent schools, where both the salaries and working conditions are better.

The shortage of science teachers and the decline in their quality must be given careful consideration at the highest government level. The resources of scientific man-power and their most effective use require reconsideration, with full recognition of the claims of the public and grammar schools. It cannot be too strongly emphasized that these schools occupy the key position in the professional life of Britain. They are the source from which the nation recruits not only its university students, but also the majority of other professional men and women, including the teachers in the primary and secondary modern schools. If the standards in the public and grammar schools be allowed to fall, this will in due course be reflected in the whole professional and industrial life of the community, with all this means for our standard of life.

The present position is that the number of suitably qualified graduates in science is strictly limited, and one profession, namely teaching, which occupies a fundamental place in the supply line of scientific men and women, is experiencing a serious shortage. If the work of technical colleges is expanded and a new technological university is opened, where will the additional staff come from? Some school science teachers are already being attracted to the technical colleges by improved salaries. It is therefore pertinent to ask whether the Scientific Civil Service and industry could economize in their use of scientific workers.

Secondly, the salaries of science teachers (and that of all grammar school teachers) should be made comparable with those offered by the universities, the Scientific Civil Service and industry. The present Burnham salary scale continues until March 31, 1954. If by that time the salary position in such schools has not improved, the present system of one Burnham Committee for all types of schools will have failed, and a separate Burnham Committee for grammar schools should be re-instituted, parallel with the separate committees both for technical colleges and for teachers' training colleges already in existence. Finally, every effort should be made by the Ministry of Education, by professional associations of administrators and of teachers, and by public opinion to induce local education authorities to restore to the grammar schools the working conditions they enjoyed before the War,

To sum up, there is at present in Britain a shortage of grammar school science teachers, and their scientific qualifications are below pre-war standard. The situation will get progressively worse and lead to a lowering of our standard of life unless prompt measures are taken. In its post-war schemes of expansion, Great Britain over-strained its resources of scientific man[illegible]wer, with the result that science in the grammar school is suffering. The position warrants a survey at the highest level of the utilization of science graduates in Britain.

A PHILOSOPHY FOR MODERN MAN

The Conduct of Life

By Lewis Mumford. Pp. ix+342. (London: Secker and Warburg, Ltd., 1952.) 21*s*. net.

THIS book completes the series which Mr. Lewis Mumford commenced with the publication of "Technics and Civilisation" and continued in "The Culture of Cities" in 1938, and in "The Condition of Man" in 1944. In this final volume the reader is given the philosophy which inspired the earlier trilogy and which gives unity to the whole ambitious project. For two decades Mr. Mumford's thought has matured, as may well be seen by comparing the final volume with two other slighter books, "Faith for Living", written in response to the challenge of the early summer of 1940, and "Programme for Survival", provoked in 1946 by the menace of the atomic bomb. These two books contain, indeed, the core of Mr. Mumford's thesis and argument expounded at greater length and more maturely in the present volume. Mr. Mumford's claim that "The Conduct of Life" is, in fact, a preface to the earlier volumes of the series thus seems a little thin, but there is justice as well as logic in his contention that the full import of any one book cannot be grasped without an understanding of the other three. To some extent they overlap and are interdependent, and the admirable bibliographies are planned to be complementary so as to avoid overlapping.

Like "Faith for Living", "The Conduct of Life" is a confession of faith and a tract for the times. As such it is acceptable, where from a strictly philosophical point of view it might be found deficient. Even from that point of view it is a better and more mature book than "The Condition of Man". It is free from the tendency to dramatize and over-simplify the issues which in earlier books in the series masked the historical continuity and, especially with his predilection for dramatic captions and juxtapositions, frequently distracted or irritated the reader. The pattern of life clearly to be traced in those earlier books is here set forth in the context of some discussion, comprehensive but not exhaustive, of the final problems of man's nature, destiny and purpose, and the measures required to further that pattern are argued afresh in the light of the changes for the worse which have occurred throughout the world since Mumford began to write these books.

Mumford opens with a revolt against the idea of automatic progress through scientific advance and of the mechanical conception of life with its disregard for human personality. This seems to flow naturally from two brilliant chapters in "Technics and Civilisation" in which he discussed the assimilation of the machine and the reorientation of life on lines which gave full expression to human personality and made man once more the master and not the servant of the machine. Once again he diagnoses the present situation to show the challenge it offers to renewal, insisting on the need to concentrate all the resources our society possesses, all its present energies and vitality, and its funded values and ideas on the upbuilding and regenerative functions, in both the personality and the community. Such a process of renewal, he argues, holds our only hope of escaping catastrophe, and he then proceeds to analyse what is involved in such a reorientation to life. That analysis leads him to a discussion of man and his nature and the transformation of man, in which Mumford sets forth his ideas on ethics and religion much as he did in "Faith for Living". Philosophically, his argument seems somewhat superficial, but his plea for self-understanding and for a moral foundation is argued with a sincerity that commands respect even when agreement is only partial, and he gains strength as he goes on to delineate the basis for human development and to diagnose the obstacles which have to be removed or surmounted. On the fulfilment of man and the drama of renewal he writes with an assurance that is never more fluent and convincing than when he expands his views on the need for balance and discipline—views which are similar to those Dr. K. E. Barlow set forth in "The Discipline of Peace". Here, even more than in his earlier books, Mumford reveals how much his thought has in common with Smuts's conception of holism, and his discipleship of Geddes is as marked as in a much slighter tract for the times, "The Social Foundations of Post-war Building", in which he expounded views which are set forth more fully here and in "The Culture of Cities". Mumford is never happier, too, than when he touches on the world of science: his book is supremely a sermon against extremism and rigid institutions in systems. He denounces as folly both the effort to increase productivity or output without regard to the effect on human personality, and a blind trust in the wisdom of the masses. The first step towards freedom, he argues, will be a new respect for the symbol, a purification and clarification of language itself, an abstention from the unclean slogans which are so cunningly employed by totalitarian regimes. "The death of the advertising agency and the propaganda bureau will be one of the surest signs of the birth of a new society."

Mumford pleads for thought, for the will and the means to direct the instruments we have created in the interests of life, so that we can contract them and bring them to a halt when they threaten that life. Discrimination and selection are essential elements in his programme, and he places in the forefront the cultivation of a sensitivity and a tenderness to human needs and personality to which the welfare State, no less than the totalitarian, is markedly indifferent. That is one reason for his sternness to those who reduce life to a rigid system: planning has its place, but strictly as the servant of man, and Mumford raises his voice against the barriers that have been erected in these years against the free interchange of opinions, the free rivalry of opposing beliefs, the free flow of ideas, as he does against subservience to all anodynes that impair our power of choice and judgment, whether the cinema, the television set, alcohol, tobacco or drug addiction. "The majority is probably wrong" might well be his reply to some of the slogans of to-day or to those who think modern man can do no wrong.

The development of evaluation and selection, of a constant discrimination between good and bad, as an inherent need of human life, is one of Mumford's three main criteria for an ethics of human development. Reverence for human life in all its manifestations is another: he examines at some length Dr. Albert Schweitzer's principle, which he commends without unreservedly accepting its theological connotation. Third is the acknowledgment of the purposive nature of all living processes and the conscious formulation of ideals, goals and plans as an essential transition of natural teleology into the development of man.

Mumford's distrust of rigid systems is a basic thesis of the book; more positively this is the affirmation of organic life in what he calls the principle of balance—a balance and harmony, sufficiently dynamic and comprehensive to nourish every kind of nature, to create the fullest variety in unity and to do justice to every occasion. It is this principle he finds incarnate in Schweitzer, and, following the latter's argument that no present form of science or political or religious organization can avert the disintegration of civilization, Mumford postulates, as the first condition of renewal, a withdrawal from society to gain the self-knowledge and concentration which are the prelude to effective action and to a balanced life characterized by health, poise and sanity, and renewed faith in the creative processes and in values and purposes that transcend past achievements and forms. What he advocates here is not asceticism as such but rather something akin to the wise administrator's practice of making time for creative thinking, free from routine duties.

In this way, Mumford suggests that the individual will regain the vision and initiative to make him an active and effective member on rejoining his group. Confidence in this prescription is derived by Mumford essentially from Clerk Maxwell's doctrine of singular points. "At these points, influences whose physical magnitude is too small to be taken account of by a finite being may produce results of the greatest importance. All great results produced by human endeavour depend on taking advantage of these singular states when they occur." Mumford believes in the possibility of the singular point, though he gives no indication as to how these points can be fostered.

In that possibility he finds the first reason for the faith and sense of purpose that he considers as essential for the development of man and the regaining of control over events. His second reason is in the sense of historic continuity to which his mature thought has led him. He starts with human life in its historic manifoldness and purposefulness: "Before every attempt to describe the world and life and time there stands an unspoken prologue: human history itself. . . . To understand the nature of man, accordingly, we must first of all understand this prologue". Mr. Mumford has now discovered not merely that man needs a religious as well as a moral view of the universe, but also that there are more primordial elements of human experience than matter or motion. Man lives in history and through history —in a sense he lives for history; and from this Mr. Mumford derives the faith that enables him to face the task of renewing civilization, even if, while recognizing the noble elements in the great world religions, he cannot entirely accept any of them. For him God is still in the making. There are occasional lapses in balance or judgment—as, for example, in the reference to Neville Chamberlain or the apparent bracketing of Schweitzer with Weston—but these do not impair the dignity of a courageous and inspiring book, a book which stimulates reflexion and self-examination and which, as a subsidiary merit, includes a select bibliography forming a reliable guide to representative books for further reading.

R. Brightman

HORMONES, CHEMOTHERAPY AND ANTIBIOTICS

Medicinal Chemistry

Chemistry, Biochemistry, Therapeutic and Pharmacological Action of Natural and Synthetic Drugs. By Prof. Alfred Burger. Vol. 2. Pp. xv+579–1084. (New York and London: Interscience Publishers, Inc., 1951.) 10 dollars.

This second and final volume of Prof. Alfred Burger's treatise follows the same pattern as the earlier volume, the review of which (*Nature*, 168, 438; 1951) contains general comments which are applicable here also. In the main, this volume is concerned with synthetic drugs used in the chemotherapy of diseases caused by pathogenic organisms and with antibiotics. The author evidently wished his treatise to be fairly comprehensive and has included a description of vitamins and hormones; but he seems to have had difficulty in fitting these into his scheme. The vitamins were discussed in the first volume, although they have little relationship to the other classes of drugs dealt with there, whereas the present volume contains a chapter on hormones (mainly steroid) which seems a little out of place in relation to the other contents.

In his preface the author comments on the increasing activity in several fields during the year of publication, and he found it difficult to incorporate all the latest developments. This is inevitable with a rapidly advancing subject, and in the period which has elapsed since publication there have been further important developments. This applies especially to the adreno-cortical hormones, in connexion with which the past two years have witnessed much feverish activity culminating in their total synthesis; in improved methods of partial synthesis from more abundant plant and animal steroids; and in elucidation of some of the likely stages in their biosynthesis. In the field of antibiotics also there have been important advances, of which perhaps the most interesting is the recent claim to have established the structures of aureomycin and terramycin as hydronaphthacene derivatives (Woodward *et al.*, *J. Amer. Chem. Soc.*, 74, 3708, 4976; 1952). The quest for new antibiotics seems to attract the big battalions. One learns from Prof. Burger's book that the first announcement of the discovery of aureomycin was made by forty-three authors, and that one of the earliest papers on terramycin appeared under the names of no less than eighty-five authors.

It is unfortunate that the discovery of valuable new therapeutic agents tends to be over-publicized, with exaggerated claims which lead to inevitable disappointment. This has happened many times in the history of therapeutics. Cortisone has been shown to be less generally efficacious in the treatment of rheumatoid arthritis than was originally thought; this and its undesirable side-effects have now led to the situation that the supply seems to have outstripped the demand. Recently the Americans have been considering imposing a ban on the use of chloramphenicol (chloromycetin), for although it has been used successfully in the treatment of rickettsial diseases, there have been indications that it may produce a dangerous condition of aplastic anæmia. In spite of such disappointments, there is probably every justification for Prof. Burger's statement (p. 658) that "the last fifty years of chemotherapeutic research have helped medicine more than the efforts of all scientists in the preceding 5000 years".

In addition to the chapters on hormones and antibiotics, the present volume contains chapters on essential amino-acids and fatty acids, dyestuffs used in chemotherapy, sulphonamide drugs, antimalarials, antitubercular and antileprotic agents (in both of which fields there have been subsequent developments), trypanocidal, amœbicidal and antifilarial drugs, organometallic compounds of arsenic, antimony, and bismuth, and antiseptics. There are available more extensive works on most of these subjects, but it is useful to have an excellent account of them all in one volume. An attempt has been made to present the views which have been advanced as to the mode of action of the drugs, and there is, for example, a chapter devoted to a discussion of theories of metabolite antagonism.

In its production this volume reaches the excellent standard set by Vol. 1, and there is a good index covering both volumes. There are a few misprints, such as "typtophan" (p. 581), and "persued" (p. 699). It is questionable whether "stereoisomerize" should be used as a verb (p. 627), but "grignardize" (p. 622) is an abomination. Exception could be taken to other points of detail; but as a whole the book is very readable and contains a wealth of useful information.

J. W. Cook

PLANT VIRUSES, OLD AND NEW

Plant Viruses and Virus Diseases

By F. C. Bawden. (Plant Science Books, Vol. 23.) Third, entirely revised edition. Pp. xvi+336. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1950.) 6 dollars.

THE modern study of plant viruses involves the use of varied techniques and ramifies through much of the whole field of natural science. It is therefore a formidable task for any one investigator to collect together all the relevant information from such a wide field and present it in an intelligible and readable form. That Mr. F. C. Bawden has succeeded so well in his task speaks well for his grasp of the subject. During the past decade, with the development of new techniques and methods of approach to the problem, our knowledge of the plant viruses has expanded so rapidly that any books on the subject become quickly out of date. The author has realized this and in consequence has virtually rewritten the third edition of his book, adding a new chapter on quantitative methods of virus assay. There are now seventeen chapters, and they deal with external and internal symptoms of infected plants, methods of transmission, relations between viruses and vectors, mutation and interference between strains, serological relations, quantitative methods of assaying for viruses, their purification and chemical and physical properties, crystallinity, estimation of particle size, types of inactivation, taxonomy of viruses, physiology of host plants, control measures and speculations on the origins of viruses.

This list of contents shows how completely the subject is covered, though perhaps, by the time the next edition is called for, knowledge will have progressed far enough for a chapter on the multiplication of viruses to be added. One of the most interesting chapters is the last, in which the author discusses the origin of viruses. Like most plant-virus workers, he is struck with the appearance of new virus diseases which "are being described with an almost frightening frequency". On p. 321 he says: "it is probably to tolerant organisms we should look for the origin of our current pathogens". This brings up the question of the origin of these 'new' viruses, which is fundamental to the whole problem. It may not be too revolutionary, in view of the modern trend of virus work, to suggest that one explanation may be the transfer, usually but probably not always by insect agency, of cellular constituents from one organism in which they are not pathogenic to another one in which they are. We do not know how many instances of such "cellular constituents" exist, whether we regard them as 'latent viruses' or merely as normal cell components of that particular host. The inference is that they are very numerous. The newly described latent virus of sugar-beet is a case in point. Transfer of this to the cowpea produces in outdoor plants a virulent disease. Other instances are the paracrinkle virus of King Edward potatoes and the latent virus of dodder.

Methods of detecting the presence of such latent or potential viruses are at present very crude and consist mainly of hit-or-miss trials with indicator plants. It is possible that the electron microscope will aid in this search, although the difficulties in interpreting the many virus-like particles seen in cells of apparently healthy plants are very great.

Mr. Bawden is to be congratulated on his book, which is clearly printed and illustrated with many excellent photographs. K. M. SMITH

FUNGI FOR EVERYONE

The Molds and Man

An Introduction to the Fungi. By Prof. Clyde M. Christensen. Pp. viii+244. (Minneapolis: University of Minnesota Press; London: Oxford University Press, 1951.) 21*s*. net.

THIS book is written for "beginning students in mycology, whether amateur or professional". It would certainly be most useful for such people, but it may prove to be one of the few books which present scientific facts without strain to the non-scientific reader. The language is clear and the text most interesting of itself; many narrative novels have less power to hold the attention.

There are chapters on what fungi do and how they grow, on their reproduction and dissemination, and an appendix on their classification. Discussion of fungus partnerships with other plants includes lichens and mycorrhizas of orchids and forest trees. Partnerships with animals bring descriptions of scale insects and their fungus houses, ants and fungi, ambrosia beetles, the nitrogen cycle, and the fascinating behaviour of *Pilobolus* on horse dung. Plant diseases are treated with the importance they deserve, for Dr. C. M. Christensen himself lived mainly on corn-meal mush in the winter of 1916–17, when stem rust of wheat "emptied the breadbasket of North Dakota". Typical rust diseases of various food plants and fungi which cause heart rot in trees are the two subjects chosen to illustrate the whole. Fungi also destroy stored food-products—grain, butter, meat and eggs—and they rot wood, paint, fabrics and other materials. The section on parasites of micro-organisms and insects includes an account of 'snaring' mechanisms on some fungi which trap and feed on nematodes. It also describes several entomogenous species, and considers the possibilities of biological control of insect pests. Fungal parasites of fish, land animals and man expand the total of our awareness of fungi as enemies. On the credit side, fungi add to our food, either directly, as in the cultivation of mushrooms, or indirectly, to flavour, as in Roquefort or Camembert cheese. Enzymes and acids are now produced by mycological methods, while the fascinating development of penicillin and streptomycin is discussed in the text.

Dr. Christensen is an artist with words, and his book should bring mycology much more within the orbit of an increasing body of non-specialist but discriminating readers. Why, however, does he ration his book so sparsely of illustration? The few pictorial representations which do occur suggest that he may have a wit of delineation in addition to an ease of language. J. GRAINGER

TOWARDS THE ABSOLUTE ZERO

Low Temperature Physics

Four Lectures. By F. E. Simon, N. Kurti, J. F. Allen, K. Mendelssohn. Pp. vi+132. (London: Pergamon Press, Ltd., 1952.) 21*s*.

THE four lectures in this volume were delivered at the Royal Institution, London, in February and March 1950, but the opportunity has been taken during the interval to revise the text and to bring the subject-matter up to date. The references include papers published as late as the first quarter of 1952. Three of the lectures are by leading members of the low-temperature school at the Clarendon Laboratory, Oxford, and the fourth by Prof. J. F. Allen, of the University of St. Andrews.

Prof. F. E. Simon in his introductory lecture describes low-temperature physics as one of the most flourishing parts of modern science and gives a masterly general survey of the characteristic features, with particular reference to the guiding principle of the third law of thermodynamics and the fact that quantum laws cause all systems to approach a state of perfect order. Dr. N. Kurti discusses the temperature-range below 1° K., a region which has been explored for about ten years only and for the attainment of which, being below the lowest temperature obtainable with liquid helium, methods other than that of the standard method of gas liquefaction have been devised. The magnetic cooling method is fully dealt with, and nuclear paramagnetism, which is a very recent development, is shown to be a fruitful field of investigation for the application of extremely low temperatures.

The peculiar and most interesting properties of liquid helium, many of which are still not understood, are described by Prof. Allen, and finally Dr. K. Mendelssohn deals with that equally puzzling and perhaps in some ways related phenomenon, superconductivity. Discovered forty years ago and investigated both theoretically and experimentally in great detail since, a wealth of information has been collected; but there are grave difficulties in the way of a satisfactory explanation of the phenomenon. Dr. Mendelssohn suggests that what is missing is a new concept in physics, a new form in which the particles of matter can associate. He emphasizes the curious analogy between superfluidity in liquid helium and superconductivity, in both of which, at a certain temperature, the degree of order in the system suddenly increases; and he advances the idea of a fourth state of aggregation of matter, an ordering or condensation with respect to the momenta, in addition to the three states of aggregation of positional order.

The volume should prove most useful to honours students, to those intending to specialize in low-temperature physics and to more advanced physicists who wish to obtain a clear, authoritative picture of the present position of knowledge of low-temperature phenomena. S. WEINTROUB

Introduction to the Transfer of Heat and Mass

By E. R. G. Eckert; with an Appendix on Property Values, by Robert M. Drake, Jr. Pp. xiii+284. (London: McGraw-Hill Publishing Co., Ltd., 1950.) 34*s*.

THE American edition of Dr. E. R. G. Eckert's excellent German text, enriched as it is by new sections and some fine interference photographs, is most welcome. The literature of the subject is so vast that there is need for a work such as this, which presents basic theory and established data but is chiefly concerned with depth of understanding.

The largest part of the book deals with heat transfer by convection. The starting-point is the flat plate in longitudinal flow, so that the student is immediately introduced to velocity and thermal boundary layers and acquainted with the factors which govern them. Extensive use is made of the approximate methods associated with the names of von Kármán, Pohlhausen and Kroujiline, which are simple and sufficiently accurate and which have the great advantage for the student of using physical, rather than exclusively mathematical, reasoning. Flow in ducts is treated later, as a case where the stream is all boundary layer. There is a good account of recent work on the analogy between heat transfer and friction.

Mass transfer is given less attention than heat transfer. The only case considered in detail is the transfer of water vapour between an air stream and a flat plate. A few pages devoted to generalizing the results so obtained would be a worth-while addition, contributing to the student's confidence in tackling other cases.

The treatment of radiation and radiative heat-exchange is concise and benefits from the fact that the author's own research has made important contributions to our knowledge of this aspect of heat transfer.

D. B. Spalding

Tables of the Error Function and of its First Twenty Derivatives

By the Staff of the Computation Laboratory. (Annals of the Computation Laboratory of Harvard University, Vol. 23.) Pp. xxviii+276. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1952.) 8 dollars.

IN various forms, at various intervals, and with various degrees of accuracy, integrals of the 'normal' (Gaussian) distribution function have been tabulated, mainly on account of its fundamental importance in statistical calculations. Nothing like the same attention has been given to the derivatives, although the demand for them has been increasing. They also enter into statistical calculations (for example, the Gram–Charlier series). They provide solutions of the equation of heat conduction or diffusion, are closely associated with the Hermite polynomials, and possess valuable orthogonal properties. After requests from various quarters these tables were prepared in the Harvard Computational Laboratory, under contract with the United States Air Force. It is claimed that, at any point, they give more derivatives or more decimals, or use a smaller interval, than other published tables.

Table 1 gives $\varphi_0(x) = \sqrt{(1/2\pi)}\,\exp(-\tfrac{1}{2}x^2)$, its integral (for completeness) and its first four derivatives. Table 2 gives derivatives from the fifth to the tenth. In these tables six decimals are given, at intervals of 0·004 in x, and tabulation proceeds until the values cease to be significant in the sixth decimal. Tables 3 and 4 give the succeeding derivatives, up to the twentieth. Here the larger values which occur for the smaller values of x are given to seven significant figures, but later values stop, as before, at the sixth decimal; the interval in these tables is 0·002. No reason is given for the rather unusual choice of intervals, and no special provision is made for interpolation, since the Taylor series is appropriate and not inconvenient.

An introduction gives an account of the main properties of the functions tabulated, an outline of the method of calculation, and an account of problems in which these functions have found application. Seven-decimal values of their zeros are also given.

W. G. Bickley

Copolymerization

By Turner Alfrey, Jr., John J. Bohrer and H. Mark. (High Polymers, Vol. 8.) Pp. x+269. (New York and London: Interscience Publishers, Inc., 1952.) 6.80 dollars.

COPOLYMERIZATION is the phenomenon of the synthesis of a macromolecule from two monomeric components, each of which is capable of polymerizing. Not all monomers exhibit this phenomenon, and in addition it is occasionally possible for copolymers to be formed when one of the components does not itself polymerize. Very occasionally it may happen that two molecules will form a copolymer and neither will polymerize separately. Copolymers are of great interest industrially—nearly all synthetic rubbers are copolymers because the necessary properties cannot be obtained with a homogeneous polymer made from one component only. But this volume is concerned almost wholly with the purely academic problems which arise in such processes. Most of the work on copolymerization has been induced by the addition of free radicals in the monomers, and the ionic mechanism of copolymerization has only been studied to a very limited extent.

The book presupposes some knowledge of polymerization mechanism, since this is dealt with in detail in other volumes in the series. The authors are so well known for their contribution to high-polymer chemistry that this whole book is a thoroughly critical and authoritative discussion of the reaction mechanism of copolymerization, the structures and reactivity of copolymers. The immense number of systems studied has added a very important chapter to our knowledge of relative reactivity radicals and thrown a new light on radical reactions. In spite of the specialist nature of the subject, the book will be of great interest to anyone interested in the mechanism of organic reactions. It is well produced, illustrated, printed and bound.

H. W. Melville

Geometry and the Imagination

By D. Hilbert and S. Cohn-Vossen. Translated by P. Nemenyi. Pp. ix+357. (New York: Chelsea Publishing Co., 1952.) 5 dollars.

THE original German edition of this book, "Anschauliche Geometrie", was reviewed in these columns in 1933 (see *Nature*, 132, 369; 1933). This English translation, by P. Nemenyi, retains the fascination and enthusiasm of the original work, and should provide stimulus and inspiration to every student and teacher of geometry.

CONDUCTIVITY OF THE IONOSPHERE*

By Dr. W. G. BAKER
Amalgamated Wireless (Australasia), Ltd.,
AND
Dr. D. F. MARTYN, F.R.S.
Radio Research Board, Commonwealth Scientific and Industrial Research Organization, Canberra

MORE than seventy years ago, Balfour Stewart[1], and later Schuster[2], realized that the small regular daily oscillations of the compass needle were probably produced by electric currents in the upper atmosphere. The latter put forward a detailed quantitative theory, the 'dynamo theory', which attributed these currents to the regular daily (horizontal) tidal movement of conducting air across the magnetic field of the earth. Chapman[3] showed that the postulated conducting region should have a (height-integrated) conductivity $\int \sigma dh$ of $2{\cdot}5 \times 10^{-5}$ e.m.u.-cm. at the epoch of sunspot maximum, if the tidal speed in the conducting region was the same as that found at ground-levels.

When the ionosphere was experimentally discovered, about 1925, by Appleton, and by Breit and Tuve, it was reasonable to expect that the dynamo theory of magnetic variations would soon be confirmed. Unfortunately, as experimental knowledge of this region accumulated, it seemed clear that all the various ionized layers D, E, F, taken singly or together, had insufficient conductivity to give the necessary current intensities, if these were calculated according to Schuster's theory, which assumed that the velocities of the tidal winds in the ionosphere were the same as those measured at the ground. The calculated low conductivity of the ionosphere was due mainly to the earth's magnetic field, which impedes the horizontal flow of charged particles at the low pressures existing in the upper atmosphere, as first pointed out by Pedersen[4].

This deadlock in the application of the dynamo theory to the magnetic variations remained until 1936, when Taylor[5] and Pekeris[6] showed that the atmosphere could oscillate tidally in such a way that the wind velocities in the upper atmosphere were much larger than those at the ground. Previous investigators of atmospheric oscillations had assumed two special temperature gradients: (*a*) isothermal, with isothermal expansions (Laplace), and (*b*) fully adiabatic, with adiabatic expansions (Lamb). In these two special cases, chosen by Laplace and Lamb for mathematical convenience, the amplitude of the oscillations is independent of height; it is now clear, however, from Taylor's work, that these two cases are unique, for in the general case the amplitude tends to increase markedly with height. The fundamental physical principle involved in the general case appears to be that the horizontal *energy* flow tends to be uniform at all heights; this is proportional to ρu^2, where ρ is the air density, and u the speed of tidal motion. Thus u varies as $\rho^{-1/2}$, and may be expected to be some 1,000 times greater in the ionosphere than at the ground, if damping be negligible. In parallel with this theoretical development, the discovery of the large (1-km.) lunar oscillation of the E-region of the ionosphere by Appleton and Weekes[7] in 1939 appeared to provide an experimental vindication of the dynamo theory, since it could be interpreted as showing that the lunar oscillation at 120 km. was some 6,000 times that at the ground. However, Martyn[8] showed that this oscillation of the E-region was likely to be due, not to simple tidal rise and fall of the isobaric surfaces, but to the electrodynamic forces associated with the magnetic variations; this demanded much less amplification of tidal velocities—perhaps only 200. This view has been confirmed by Weekes[9], who finds no evidence of lunar tidal winds in the E-region of velocities greater than about 200 times those at the ground. It should be pointed out also that amplifications of 6,000 would lead, for the solar tide, to winds in the ionosphere of speeds approaching, or greater than, that of sound—an unlikely contingency, and one not envisaged in the theoretical work of Taylor and Pekeris.

Cowling[10] has made a careful study of ionospheric conductivity; his findings may be summarized by the statement that a tidal amplification of several thousands is required if the dynamo theory be valid, unless there are large numbers of negative ions in the E- and F_1-regions. More recently, Bates and Massey[11] have put forward strong arguments against the existence of negative ions in appreciable numbers in these regions. They conclude that the theoretical calculated conductivity of the ionosphere is less than 4×10^{-9} e.m.u.-cm., so demanding a tidal amplification of about 6,000.

In recent years, Martyn[12] has studied the observed amplitudes and phases of the lunar semi-diurnal oscillations in the heights and densities of the various ionospheric regions. He concluded that the phases were inconsistent with the view that the lunar magnetic variations were due to currents flowing in either the E-, F_1- or F_2-regions, if these currents flowed in the direction of the local electric fields. If this conclusion be accepted, then it must follow either that these currents flow in other regions, deficient in electron density but rich in negative ions, or that the currents flow in a direction markedly different from the electric fields. Bates and Massey (*loc. cit.*), after exhaustive investigation, have shown that it is extremely improbable that ions can exist at other levels, in numbers sufficient to give the necessary conductivity, so that the first-mentioned alternative is unlikely to be permissible.

Martyn[13] suggested in 1948 that the conductivity of the ionosphere may be enhanced if transverse (Hall) currents are prevented from flowing by polarization, along lines investigated first by Cowling[14] in connexion with the solar atmosphere. However, Cowling and Borger[15] considered that this suggestion would not account for the discrepancy, save perhaps in a narrow region near the magnetic equator.

It now seems clear that in spite of the early promise of Pekeris's theoretical calculations of high-level tidal amplitudes, and of Appleton and Weekes's measurements of E-region lunar oscillations, a major difficulty still exists, in that all the combined regions of the ionosphere have apparently insufficient conductivity (by the factor of 10 at least) to account for the observed geomagnetic daily variations according to the dynamo theory.

---

* Substance of papers presented at the recent meetings of the International Scientific Radio Union and of the Mixed Commission on the Ionosphere, at Sydney and Canberra, Australia.

No satisfactory alternative to this theory exists, and it cannot be lightly abandoned, since it gives an excellent qualitative account of the magnetic variations. Moreover, an entirely different approach, by Ashour and Price[16], who have studied the induction of currents in the ionosphere, gives convincing support to the view that the average conductivity of the ionosphere is between 5 and 10×10^{-8} e.m.u.-cm., which would be adequate for the purposes of the dynamo theory.

Accordingly, we have examined afresh the fundamental principles involved in the production of electric currents in the ionosphere by tidal winds.

It is clear that the relevant conductivity cannot be σ_0, which is that appropriate for currents flowing parallel to the electric and magnetic fields, since horizontal currents must flow *across* the magnetic field in all but very limited portions of the globe. Another (lower) conductivity, σ_1, which is that appropriate for currents flowing parallel to the electric field, but transverse to the magnetic field, has been found inadequate quantitatively, as described above.

There exists another conductivity, σ_2, the Hall conductivity, which is relevant when the electric field, the current, and the magnetic field are all mutually at right angles, and when there is no hindrance (as by polarization) to the free flow of the direct (σ_1) current.

There is also still another effective conductivity, σ_3, that for currents flowing parallel to the electric field but transverse to the magnetic field, in circumstances where the Hall current is prevented from flowing by polarization.

Write

$$\omega_{e,i} = He/m_{e,i},$$

where H is the intensity of the geomagnetic field (gauss); $m_{e,i}$ are the masses of an electron and ion respectively; e is the electronic charge (taken as a positive number); $\nu_{e,i}$ are the collisional frequencies of an electron and ion with the air molecules, $\tan(\alpha,\beta) = \omega_{e,i}/\nu_{e,i}$; and N is the number of electrons (or ions) per cm.^{3}. Then the formulæ for these conductivities may be expressed in the following simple forms:

$$\sigma_0 = \frac{Ne}{H}(\tan\alpha + \tan\beta) = A(\tan\alpha + \tan\beta)$$

$$\sigma_1 = \frac{A}{2}(\sin 2\alpha + \sin 2\beta) = A\sin(\alpha+\beta)\cos(\alpha-\beta)$$

$$\sigma_2 = A(\sin^2\alpha - \sin^2\beta) = A\sin(\alpha+\beta)\sin(\alpha-\beta)$$

$$\sigma_3 = A\sin(\alpha+\beta)\sec(\alpha-\beta) \equiv \sigma_1 + \sigma_2^2/\sigma_1$$

(in the case of σ_2 it is necessary to specify the sense of the current by indicating that σ_2 is positive when H is directed along the positive x-axis and the electric field along the y-axis of right-handed axes).

Graphs of $\sigma_{1,2,3}$ (for $N = 1$) are shown in Fig. 1 at various ionospheric levels. In computing these, the atmospheric properties assumed were those adopted by Bates and Massey (*loc. cit.*); they incorporate the latest data derived from rocket measurements. In accordance with recent measurements by Shaw[17], ν_e was taken to be $2 \cdot 5 \times 10^5$ collisions per sec. at a height of 100 km. and $\tan\alpha/\tan\beta$ was taken as 1,650, in accordance with Tyndall's[18] measurements.

It is seen that σ_1 has two maxima, that at 140 km. due mainly to ions, at 75 km. to electrons. These maxima are relatively small, and they occur at heights where ionization is relatively sparse. σ_2 has one broad maximum, at 105 ± 35 km., so including all the ionization of the *E*-region; σ_3 has a pronounced sharp maximum at 100 ± 10 km. When account is taken of the known and probable electron densities at the relevant heights (Fig. 1, curve N) it is found that:

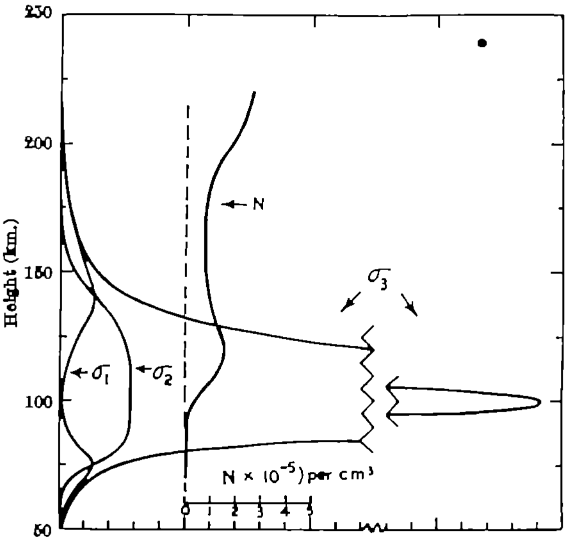

Fig. 1

$$\int \sigma_1\,dh = 4 \cdot 5 \times 10^{-9} \text{ e.m.u.-cm.},$$
$$\int \sigma_2\,dh = 1 \cdot 45 \times 10^{-8} \text{ e.m.u.-cm.},$$
$$\int \sigma_3\,dh = 1 \cdot 2 \times 10^{-7} \text{ e.m.u.-cm.}$$

Over the terrestrial sphere in general, the magnetic field is inclined to the horizontal, and to the 'dynamo'-generated electric fields. If we consider the ionosphere as a relatively thin sheet of conductive air enclosing the earth, and assume that *vertical* currents in the sheet are prohibited by polarization, then the important conductivities become σ_{xx}, σ_{yy}, σ_{xy} and σ_{yx}, the x- and y-axes running southward and eastward respectively. Here σ_{xx}, σ_{yy}, are the effective direct conductivities, and σ_{yx}, σ_{xy} the effective Hall conductivities, for horizontal electric fields in the south and east directions respectively. If χ be the magnetic dip angle, then:

$$\sigma_{xx} = \sigma_0\,\sigma_1/B, \qquad \{\to \sigma_0, \text{ as } \chi \to 0\}$$
$$\sigma_{yy} = (\sigma_0\,\sigma_1 \sin^2\chi + \sigma_1\,\sigma_3 \cos^2\chi)/B, \qquad \{\to \sigma_3, \text{ as } \chi \to 0\}$$
$$\sigma_{xy} = -\sigma_{yx} = \sigma_0\,\sigma_2 \sin\chi/B, \qquad \{\to 0, \text{ as } \chi \to 0\}$$

with $B = \sigma_0 \sin^2\chi + \sigma_1 \cos^2\chi$.

The variations of σ_{xx}, σ_{yy} and σ_{xy}, at the 100-km. level, are shown in Fig. 2 for latitudes (geomagnetic) from 0° to 90°. A logarithmic scale is used for the latitude Φ, since rapid changes take place near the equator. It will be noticed that at this height the horizontal Hall conductivity is some twenty times larger than the other horizontal conductivities over most of the earth. Within one or two hundred kilometres of the equator (magnetic), the Hall conductivity rapidly decreases, but the direct east–west and north–south conductivities rise to steep maxima.

It is readily found that a two-dimensional medium having direct conductivity σ_1, and transverse conductivity σ_2, has an effective conductivity $\sigma_1 + \sigma_2^2/\sigma_1$.

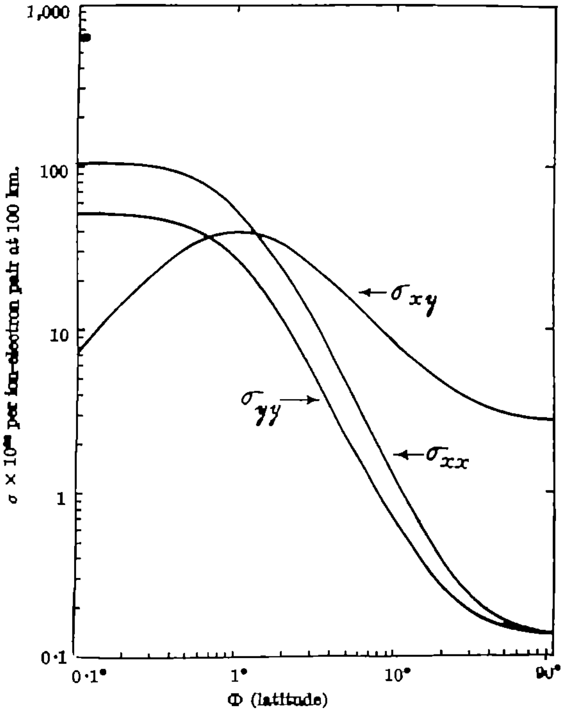

Fig. 2

In the case of the ionosphere, assuming for simplicity that $\sigma_{xx} = \sigma_{yy}$, the effective conductivity becomes $\sigma_{yy} + \sigma_{xy}^2/\sigma_{yy}$. However, although thin with respect to the earth, the ionosphere cannot be taken as infinitely thin, since σ_{xx} and σ_{xy} are variable within it. In order to assess its average conductivity, we assume that there is no height gradient of horizontal electric field; this assumption is justified by the high (σ_0) conductivity along the (nearly vertical) lines of magnetic force, which must be nearly equipotential lines. On this assumption the height-integrated effective conductivity becomes

$$\int \sigma \, dh = \int \sigma_{yy} \, dh \left\{ 1 + \left(\frac{\int \sigma_{xy} \, dh}{\int \sigma_{yy} \, dh} \right)^2 \right\}. \qquad (1)$$

At the magnetic equator, $\sigma_{xy} \rightarrow 0$ and $\sigma_{yy} \rightarrow \sigma_3$, so that:

$$\int \sigma \, dh \rightarrow \int \sigma_3 \, dh = \int \sigma_1 \, dh \left\{ 1 + \frac{\int \frac{\sigma_2^2}{\sigma_1} \, dh}{\int \sigma_1 \, dh} \right\}. \qquad (2)$$

(This expression is strictly accurate for the east–west conductivity at the equator; in this region the north–south conductivity degenerates to a somewhat higher value, namely, $\int \sigma_0 dh$ as shown above.)

In equations (1) and (2), the expressions in brackets have approximate numerical values of 12 and 29 respectively, with an uncertainty factor of about 2/1, depending on the unknown electron distribution between the E- and F_1- regions. Thus the effective conductivity of the ionosphere, over most of the earth, is some twelve times greater than that deduced by ignoring the Hall current, and near the magnetic equator is enhanced still further by an additional factor of 2·4.

Over most of the earth the currents are nearly perpendicular to the electric field, but are parallel to it near the magnetic equator. (There should therefore occur a rapid change in the phase of the daily electric field variations near this equator, a point which should have significance for the solar and lunar ionospheric variations.)

Equation (1) appears to account quantitatively for the high ionospheric conductivity necessary for the 'dynamo' theory, and would appear to justify the conclusion, after some seventy chequered years, that Balfour Stewart's 'dynamo theory' of the magnetic variations was well founded. Moreover, equation (2), which provides an additional enhancement of conductivity near the magnetic equator, is found to give a quantitative explanation of the anomalously large magnetic variations (the 'electro-jet') known to occur in these regions. (The latter conclusion has been tested by solving the dynamo equations for the spherical ionosphere, assuming the conductivity of equation (1) over most of the earth, and the narrow strip of higher conductivity at the equator.)

It appears that Martyn's earlier suggestion regarding the conductivity of the ionosphere is fully valid at the magnetic equator, and substantially valid over the rest of the earth; the earth's magnetic field reduces the conductivity by a factor much smaller than that deduced by Pedersen.

Over most of the earth, the current system should lie mainly between the 110- and 150-km. levels, the precise height distribution depending on the (relatively unknown) distribution of ionization and tidal velocities at these levels. However, near the magnetic equator the current system should be much more localized, Fig. 1 showing that it ought to flow in a shallow layer centred at 100 km. It is interesting to note that a rocket-borne magnetometer has recently been projected into the ionosphere near the magnetic equator by the U.S. Navy[19], and it is reported that the rocket passed completely through a current layer sufficiently intense to produce the observed diurnal magnetic variations at the ground; this layer was contained between the 93- and 105-km. levels.

We have discussed here the significance of our conclusions for the magnetic variations; if well founded, these conclusions are likely to have important application also to the theory of the regular solar and lunar ionospheric variations, and to the ionospheric variations associated with magnetic disturbance. These topics will be discussed elsewhere, in association with the detailed presentation of the above results.

DYNAMO CURRENTS AND CONDUCTIVITIES IN THE EARTH'S UPPER ATMOSPHERE

By Dr. S. F. SINGER

EXPERIMENTAL evidence has been obtained recently concerning magnetic discontinuities in the *E*-layer of the ionosphere near the magnetic equator[1]. This communication deals with the conclusions which can be drawn from these results about electric currents and D.C.-conductivities in the *D*- and *E*-layers of the ionosphere and their relation to ΔH, the diurnal variation of the magnetic field on the earth's surface.

Rocket measurements. With magnetometers mounted in 'Aerobee' high-altitude sounding rockets[1], we have made three separate measurements of the variation of the earth's magnetic field with altitude from sea-level up to 105 km.[1,3]. An electronic magnetometer of the saturable 'Permalloy'-core type was used in each of the three rocket flights; in order to make its reading independent of the orientation of the rocket, it was designed to measure the scalar value of the total field rather than any one component. The small magnetic influences of the rocket were carefully neutralized; the magnetometer sensitivity was determined periodically by means of in-flight calibrations; and the output of the instrument was telemetered by radio to ground receiving stations. A detailed description of the apparatus is given in references 1 and 3.

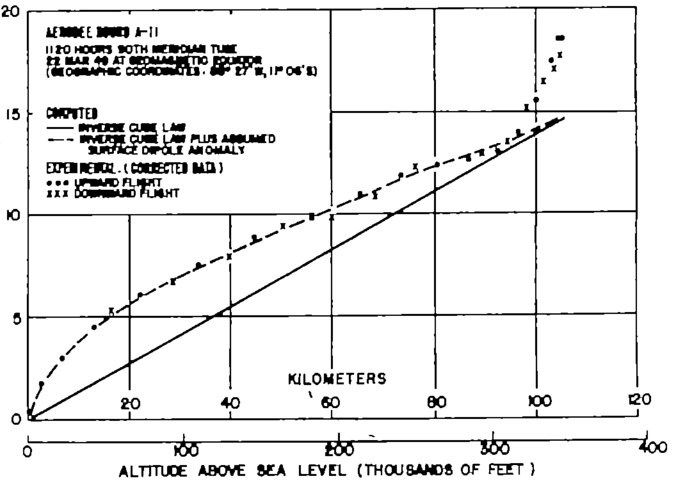
The initial attempt[3], conducted in April 1948 at the White Sands Proving Ground, New Mexico (geomagnetic latitude 41° N.), was designed mainly to test the instrumentation and the feasibility of the scheme. The decrease of the earth's field was found to be in excellent accord with the fall-off calculated from spherical harmonic analysis of the sea-level field[4]. No evidence either for or against a magnetic discontinuity could be established because of the smallness of the effect at this latitude.

Two further measurements were then carried out near the magnetic equator[1] (about 1,000 miles west of Huancayo, Peru) in rockets launched from the U.S. Navy seaplane-tender U.S.S. *Norton Sound*. The first rocket was fired on March 17, 1949, in the late afternoon, at which time ΔH is very small. Except for the effect of a small surface anomaly, the observed decrease of the magnetic field with altitude was in good accord with the inverse cube law; no detectable magnetic discontinuity was encountered.

The second rocket was fired near noon on March 22, 1949, close to the time of the maximum of ΔH, about 100 km. from the location of the first rocket launching. The deviation of the field from the inverse cube law (see graph) up to about 90 km. can be reproduced by means of a suitably *assumed*[2] surface anomaly. An interpretation in terms of a current—although this has an *a priori* possibility—does not appear justified.

Between 93 km. and 105 km. we observe a very rapid decrease in the magnetic field amounting to 4·0 ± 0·5 milligauss. The agreement of upward and downward points is within 0·5 milligauss or better. We interpret this decrease as produced by a current flowing from west to east in a sheet of large horizontal extension which commences at 93 km. and extends to an altitude of at least 105 km. in a rather uniform manner. (The accuracy of the measurements is not sufficient to obtain the detailed current distribution within this altitude interval.) We have no direct experimental knowledge of the strength or direction of the current *above* 105 km., the peak altitude reached by the rocket (but cf. 4 below).

Experimental deductions. These experimental results allow us to draw some conclusions about certain electrical properties of the earth's upper atmosphere.



(1) They establish by direct experiment the existence of a current system which is presumably responsible for the exceptionally large diurnal variation of the earth's field observed at Huancayo.

(2) The location of the current is found to be in the lower portion of the *E*-layer of the ionosphere; this fact lends further strong support to the dynamo theory[5] originally proposed by Balfour Stewart[6] in 1883 to account for the production of the current system which was inferred by him from the diurnal variation of the earth's magnetic field.

(3) The results do not bear out the existence of any appreciable current in the *D*-layer such as had been proposed by Martyn[7]. (A similar conclusion has been reached by Bates and Massey[8] in quite a different way, namely, by showing in detail that the maximum negative-ion concentration, and hence conductivity, in the *D*-layer would be too low.) Further measurements will be required to establish with certainty the distribution with altitude of the currents responsible for the exceptionally large lunar effect on the quiet-day solar (S_q) diurnal variation at Huancayo.

(4) It appears that the current must drop to zero rapidly just above 105 km. (unless we assume a counter-current to flow at a higher altitude). We

---

* On leave from the Applied Physics Laboratory, Johns Hopkins University, Silver Spring, Md.

reach this conclusion by comparing the amount of discontinuity—4 milligauss—with the sea-level variation of 2 milligauss observed at Huancayo. It is reasonable to suggest, therefore, that the electrical conductivity falls to zero rapidly above 105 km.

(5) The most striking feature of these results is the fact that the total current is confined to such a narrow range of altitude. We cannot account for this high value of current density ($2 \cdot 5 \times 10^{-16}$ e.m.u./cm.^{2}) if we assume in the conventional manner that the presence of a transverse magnetic field radically decreases the conductivity. At the magnetic equator the usual method of calculating the (west–east) D.C.-conductivity (parallel to the e.m.f. and transverse to the horizontal earth's magnetic field) leads to a value of 5×10^{-16} e.m.u. at the level of maximum electron density[8]. From the *observed* current, on the other hand, we can calculate an average conductivity of 10^{-13} e.m.u., using commonly accepted figures for high-altitude winds and the resulting e.m.f.'s.

(6) Thus the experimental value corresponds closely to 6×10^{-13} e.m.u., the value of conductivity calculated for the level of maximum electron density ($1 \cdot 5 \times 10^5$ per c.c.) in the absence of a magnetic field.

Hall effect. This discrepancy of almost a factor 1,000 between the observed and conventionally calculated conductivities can therefore be removed by ignoring the magnetic field.

It is well known[10] that this procedure is justified under suitable boundary conditions. In crossed electric and magnetic fields both ions and electrons will drift in the same direction (perpendicular to both fields), the electrons at a much higher speed. The resultant Hall current may set up a polarization sufficiently large to stop further current flow; once this transient Hall current ends and the polarization is established, any influence of the magnetic field on the conductivity parallel to the applied electric field is removed. Martyn[11] has suggested that this effect should be considered in calculating the conductivity of the ionospheric layers (although in the case of the D-layer at 75 km. the increase brought about by neglecting the magnetic field will be quite small). Cowling and Borger[12] have pointed out that, due to leakage, the polarization field may not build up sufficiently to keep a substantial steady-state Hall current from flowing and so result in only partial cancellation of the effect of the magnetic field. However, at the equator conditions may be favourable for almost complete cancellation, since the Hall current there flows perpendicularly to a horizontal magnetic field; hence a vertical polarization could be set up along a narrow equatorial strip where it would leak away only very slowly.

Conclusions. The results of the equatorial rocket measurements thus support the existence near an altitude of 100 km. of a layer of greatly increased conductivity, probably produced by Hall polarization. This finding is in accord with Hirono's[13] prediction of a narrow, highly conducting region at the equator; it may thus account for a substantial part of the so-called anomalous S_q variation at Huancayo.

Recent detailed measurements by Giesecke[14] of the latitude-dependence of the range of the diurnal variation ΔH have established the existence of a curve with maximum near Huancayo which is much more narrowly peaked (half-width 7°) than hitherto supposed; the main features of the curve probably persist all along the magnetic equator independent of longitude. Chapman has represented this 'abnormal' peak in a phenomenological way by superimposing on the normal dynamo current system (deduced from non-equatorial stations) an additional high-intensity current of small horizontal extension flowing only at the equator, which he terms 'electrojet'. So far no certain deductions have been possible about the dimensions, and particularly about the height, of the electrojet from sea-level observations of the magnetic elements. We cannot, therefore, exclude the possibility of interpreting Giesecke's data in terms of increased equatorial current produced by the increase in conductivity, plus the Hall polarization leakage currents. Hence the electrojet may not require any special physical mechanism, but may be understood purely on the basis of the dynamo theory.

It should be pointed out that the conclusions presented here are based on a single rocket flight, at only one location, on a disturbed day (C-index 1·8). It would be very desirable to repeat and extend these measurements of the Balfour Stewart currents in a series of rocket flights to higher altitudes, both on magnetically quiet and disturbed days, and also at various phases of the moon in order to establish the distribution of the lunar portion of the currents. The instrumentation has now been improved sufficiently to make it possible to obtain the detailed distribution of the current with altitude with considerable accuracy.

We wish to thank Prof. H. Alfvén, Prof. T. G. Cowling, Mr. W. R. Piggott, and in particular Dr. M. H. Johnson for valuable discussions. [Aug. 15.

COLOUR TELEVISION

THE sixty-seventh science meeting of the Physical Society Colour Group, held on May 14, was devoted to a discussion on visual problems in colour television. Fortunately this followed immediately on Prof. W. D. Wright's return from the United States, where among his other commitments he had discussed and witnessed demonstrations of various American colour television systems. He was therefore able to give the meeting first-hand impressions of the very considerable developments in this field on the western side of the Atlantic.

The proceedings were opened by Mr. R. G. Horner, who gave a comprehensive survey of the more feasible methods at present available for producing a colour television picture. All these are based on the conventional system of interlaced scanning, the main differences between the systems at present under discussion being in their colour scanning sequences, which fall broadly under three headings: (a) field sequential systems, (b) line sequential systems, (c) dot sequential systems. Of these, the first and third are actively in competition in the United States; so far, there has been no real evidence of success with the second system, which appears to embody the disadvantages of the first one without the compensating advantages of the third.

In the field sequential system the picture is scanned in a succession of red, green and blue fields, and, in order to reduce flicker, it is necessary to increase the field scanning-rate by approximately three times. As the colour-changes in this system take place at relatively low speeds, it is possible to produce them by the simple and cheap expedient of revolving synchronous disks containing red, green and blue colour filters in front of the television camera and receiver cathode-ray tube. However, due to the increase in field scanning frequency, an existing monochrome receiver would be unable to receive a colour transmission even in monochrome without considerable modification to its scanning circuits.

The dot sequential system involves the most rapid rate of change of colours, so rapid, in fact, that one school of thought considers the latest form to be a truly 'simultaneous' transmission of the three primary-colour signals. While this system involves the very difficult technical problem of colour-changing at a rate of several millions per second, it offers the great advantage of requiring no change in scanning-standards, and could therefore be grafted on to an existing black-and-white system and be received in monochrome on existing receivers. Mr. Horner explained that this 'compatibility' feature is very important in the United States, where more than ten million receivers are already in the hands of the public, and programme sponsors have to be assured of the continuance of their audience when changing over to colour.

At first sight it would appear necessary to transmit about three times as much information per second for a colour picture as for a monochrome one of the same sharpness. The amount of fine detail in the picture can obviously be reduced and exchanged for colour if it is desired to keep the rate of transmission of information (band-width) constant. To a certain extent this has been the procedure adopted for recent demonstrations of the field sequential system in the United States by the Columbia Broadcasting System. The loss of sharpness incurred has been partially recovered by a new receiver circuit development known as 'crispening', and very satisfactory colour pictures have been demonstrated.

In the latest form of the dot sequential system demonstrated by the Radio Corporation of America and Hazeltine, it has been found possible to recode the three electronic primary-colour signals to give a brightness component similar to that transmitted in existing monochrome systems, the colour information being transmitted by two 'colour-difference' signals which are analogous to the familiar two dimensions of the C.I.E. colour triangle. This has been called the 'by-passed monochrome' system. As the eye is insensitive to colour in fine detail, it is therefore possible to reduce the band-width (sharpness) of the two colour-difference signals. This manœuvre is one method of achieving what is known as 'the principle of mixed highs', and permits considerable saving in band-width without apparent loss of picture quality. Further band-width reduction is being explored by interleaving the colour signals with the monochrome signal, by a method which was originally a 'dot interlaced' system and more recently a 'colour sub-carrier' system. Two other American developments were referred to—the 'constant luminance' system and 'colour phase alternation'—which are refinements directed towards the reduction of spurious patterns produced by interfering signals and reduction of colour distortion.

Mr. Horner concluded his remarks by describing various solutions to the problem of changing the colours at the very high frequency necessitated by the dot sequential method. This problem is much less serious in the transmitter than in the receiver, where the question of initial cost and maintenance of the viewers' equipment is obviously an important economic factor. So far, the most successful solution appears to be the RCA tricolour cathode-ray tube. This tube contains three guns, the electron beams of which are brought into coincidence on a fluorescent screen consisting of a mosaic of triangular groups of red, green and blue phosphor dots, a total of some six hundred thousand being contained in the picture area. Between this and the electron guns, an apertured mask is accurately positioned. Each aperture centres on a group of three phosphor dots, the direction of arrival of the three beams being such that, after they have passed through the aperture mask, each beam can only excite one set of colour phosphor dots. This solution obviously involves the problem of the correct registration of the three electronic pictures on the screen of the tube. The experimental manufacture of these tubes by RCA is a major technical triumph, but many people feel that it is likely to be a very expensive design for production.

Following Mr. Horner's description of the various colour television systems, Mr. L. C. Jesty described and demonstrated some of the visual problems arising. First, with the field sequential system, the field scanning-rate has to be sufficiently high to eliminate flicker and 'colour break-up'. This was demonstrated by means of a variable-speed colour-filter disk rotating in front of a projector. With the disk running sufficiently fast to eliminate flicker, 'colour break-up' still remained and showed itself in two ways. If the viewer inadvertently moved his eyes, he saw a sequence of partially overlapping red, green and blue images. Experience has shown that the average person quickly learns to ignore this, and it is not considered to be a serious defect in the system. If an object in the picture moves rapidly across the screen, however, an effect is produced which cannot so easily be ignored. An exaggerated example of this was demonstrated by illuminating a wheel having white spokes with the projector and rotating colour-filter disk. In addition to the contrary rotation effect occurring at certain critical speeds of the wheel (as commonly seen on cinema pictures), some very striking colour patterns were produced by the spokes. A 'Kodachrome' transparency photograph of an actual field sequential colour-television picture of the wheel was then projected. This showed the same brilliantly coloured spokes, thus confirming the demonstration.

With the compatible colour sub-carrier system at present being investigated in the United States, the method of signal compression results in the appearance of a 'dot crawling' pattern on parts of the picture under certain conditions. In earlier experiments the band-width compression was achieved by simple dot-interlacing, which gave a theoretical improvement equal to halving the band-width for the same picture-detail, but at the expense of four scanning fields instead of two for the transmission of all picture elements. The resulting dot crawling or 'twinkle' on the picture and the production of additional spurious patterns from objects containing certain types of fine detail were demonstrated to the meeting in an exaggerated form by a 16-mm. film which had been recorded from the receiver screen of an experimental dot-interlaced monochrome television system. In the latest American experimental colour receivers dot patterns are now practically invisible over large areas of uniform brightness and colour, due to improvements in the method of coding the colour information.

As a final demonstration Mr. Jesty showed some colour pictures which had been kindly prepared for him by Ilford Limited (Mr. Horner), demonstrating the principles of 'by-passed monochrome' and 'mixed highs'. Two colour pictures were shown side by side for comparison, one being a normal colour transparency projected on to a screen; the other consisted of a black-and-white photographic enlargement from the original colour picture, which was illuminated by projection from a special colour transparency. The latter had been prepared by re-photographing the original colour picture with colour-sensitive material, using a black-and-white negative 'mask' of suitable quality to cancel out the greater part of the brightness differences in the colour picture. It was seen that, when this second transparency was in focus and registered with the black-and-white enlargement, it was almost indistinguishable from the normal picture alongside it. The special transparency was then progressively defocused by adjustment of its projector lens, and with certain types of picture it could be thrown badly out of focus with no noticeable loss of picture quality. The projector lens mount had been previously calibrated in Mc./s. on the basis of the B.B.C. 405-line 3-Mc./s. picture standard. The demonstration showed that the colour components of the image could be defocused well below 1 Mc./s., so long as the brightness (black-and-white) component of the image remained sharp.

Mr. Jesty concluded his remarks by stressing the necessity for a proper appraisal of alternative systems by a team of average observers, due care being taken to ensure they do not become especially skilful in their judgment, thus losing their average status.

Prof. Wright then reported on his American visit. Of the various colour television demonstrations he had seen, the field sequential system is in the most advanced state, and has given the best picture quality. He felt, however, that the potentialities of the dot sequential system are greater, particularly with regard to band-saving techniques such as in the application of the 'mixed highs' principle and, of course, in 'compatibility'. He was inclined to query if any loss in absolute definition could be tolerated in exchange for the addition of colour. He was very impressed with the technical achievement in preparing the phosphor mosaics, and in locating the mosaics, aperture mask and the three gun electrodes in correct alignment in the manufacture of the RCA tricolour cathode-ray tube.

The American television engineers have completely absorbed the C.I.E. colour triangle and are applying it with ingenuity to their colorimetry problems. Doubts are, however, beginning to arise as to the relevance of the C.I.E. data to all their problems, and colorimetrists are already becoming aware of the impact of the ideas of electronic engineers. Much remains to be learned on the subjective aspects, and the work already done in colour photography is being carefully studied. The use of an illuminated surround to the picture is being actively investigated in one laboratory. An example of the direct application of trichromatic theory to colour television is to be found in the 'low flicker primaries' used in the Columbia Broadcasting System field sequential demonstrations. By the choice of a desaturated blue primary in the receiver, they have been able to increase picture brightness without increasing flicker. The range of reproducible colours is thereby diminished, but this does not appear to give any noticeable reduction in picture quality. Again, it is possible in principle to make colour transformations from one trichromatic system to another, by means of suitable electrical circuits, and it is proposed to take advantage of this by transforming the output signals of the red-, green- and blue-sensitive cameras at the transmitter, to give correct red, green and blue modulating signals at the receiver, without the need for devising cameras having partly negative spectral sensitivity curves.

A recent American development is the Lawrence-Paramount tricolour tube. The screen of the tube consists of a fine grid of coloured phosphor lines, and close to this and accurately registered to it is a mesh of parallel wires, alternate wires being connected together. There are in effect, therefore, two interlaced grids. By applying suitable potentials to these, it is possible to deflect the electron beam on arrival so that it excites the required set of colour lines.

Following the three introductory papers, the meeting was thrown open for general discussion. Several speakers raised points relating to methods of exchanging picture-sharpness for colour. The general conclusion seemed to be that the eye is more sensitive to luminance differences than colour differences in regions of fine detail, particularly in actual television programmes, where other overriding distractions are present. If it is necessary to show detail colour as, for example, in a woven fabric, the technique of the 'close up' is available and would deal very adequately with any such requirement.

Dr. J. A. Darbyshire discussed the secondary advantages arising from the addition of colour to a picture, and demonstrated these by projecting some of his own colour transparencies. Colour can add materially to the impression of depth in a picture. For example, the colour of distant objects is often modified by atmospheric effects. Colour differences make small objects in the picture more visible, thus giving an impression of greater sharpness, not directly related to 'resolving power'. It can produce an atmosphere or mood which increases the viewers' appreciation, as, for example, the difference in the same scene viewed in the daytime and at sunset. The effect of adapting conditions on the choice of white in a picture was discussed by Mr. H. G. W. Harding. With a colour television receiver it would be possible to adjust this for viewing by daylight and by artificial light. Mr. G. T. Winch described his binocular viewing experiments for the appraisal of artificial illuminants. This technique might be applied to determining the best colour balance for television pictures. It was certain that faithful reproduction would not be acceptable. Dr. W. S. Stiles directed attention to the latest American proposals for a compatible system, where the reduced-definition red and blue colour-difference signals are equal in band-width. Further economies could be effected if the blue colour-difference signal were reduced in definition still further. The meeting having exceeded its time limit, the chairman was forced to bring to a conclusion a still lively discussion of an obviously interesting topic. L. C. JESTY

OBITUARIES

Sir Charles Peers, C.B.E., F.B.A.

SIR CHARLES REED PEERS, born in 1868, will be principally remembered as chief inspector of ancient monuments in the Office of Works. Educated at Charterhouse and King's College, Cambridge, he received his architectural training in the office of Sir T. G. Jackson. Peers's principal interest lay in the historical side of his profession, and he was for many years architectural editor of the "Victoria County Histories". As such he was responsible for the description of a number of important buildings, among which the scholarly and lucid accounts of the cathedrals at Winchester and Peterborough may be noted. With this experience he was an obvious choice when an inspector of ancient monuments in the Office of Works was appointed in 1910. Three years later the Act of 1913 was passed and Peers became chief inspector. The next twenty years, apart from the interruption caused by the First World War, were spent in building up and directing the services required to give effect to the provisions of the Act.

The Act of 1913 empowered the Office of Works to take over buildings, other than churches in use and inhabited houses, in order to ensure their preservation. In carrying out this work, Peers's aim was to preserve what time had left without unnecessary additions or conjectural restoration. The success with which he pursued this conservative objective may be judged both from the numerous abbeys and castles for which the Ministry became responsible during his period of office, and also from the virtual cessation of the bitter controversy between the different schools of preservation, which had vexed the end of the nineteenth and the early years of the twentieth century. While it would be too much to claim that there is no criticism of the work carried out under his guidance, it is essentially a criticism of details; the main tradition which he founded is unchallenged.

Research was not a primary duty of the service established by the Act of 1913, but throughout his tenure of office Peers strove to promote the publication of works that would rouse interest in the buildings under his care. For specialists there were learned articles in scientific journals such as *Archæologia*, the *Antiquaries Journal*, and many others. For the wider public there was the admirable series of official guides to the monuments in charge of the Ministry, a series of which the larger part were from the hand of the chief inspector himself. On retirement from the Civil Service in 1933, his experience was made available to other bodies. He became surveyor of Westminster Abbey, and consulting architect to a number of important buildings such as York Minster and the Cathedral and Castle of Durham.

Peers was associated from the beginning with the work of the Royal Commission on Historical Monuments and became a commissioner in 1921. His connexion with the Society of Antiquaries was long and intimate; he served successively as secretary, director and president, and was continuously an officer from 1908 until 1934. His death has come at a time when the cause in which he spent his working life is firmly established and in good hands, a result largely due to the excellence of the foundations which he laid. C. A. RALEGH RADFORD

Mr. S. R. Roget

SAMUEL ROMILLY ROGET died on November 17 in the way he would have wished, suddenly and while in full harness. In spite of his seventy-seven years, he was actively engaged, on a full-time basis, in work dear to his heart—the preparation of national and international glossaries on electrical and other technical subjects. His keen interest in this sort of work is, of course, well known; not only did he publish a "Dictionary of Electrical Terms", but also he kept up to date the famous "Thesaurus of English Words and Phrases" which was compiled by his grandfather, Dr. P. M. Roget, and first published in 1852.

Born in London in 1875, the great-grandson of a Genevese Protestant minister who came to England to be the pastor of a London Huguenot Church, Samuel Roget was educated at University College School. He studied mechanical sciences at Cambridge, and after a further year of experimental work at Cambridge went to the Woolwich works of Siemens Brothers. He remained there for seven years and then turned his attention to technical journalism. He was for a time assistant editor of the *Electrician* and afterwards of *Electrical Engineering* (of which he was part-proprietor) from 1906 until 1917, when publication ceased. Between the two World Wars he was a 'free lance' and occasionally contributed to *Nature* and other journals. He also did abstracting work for the Institution of Civil Engineers and the Institution of Electrical Engineers.

As befitted his Huguenot descent, he was a member of the Huguenot Society of London and became its honorary secretary in 1923, a post which he held until he was elected president in 1951.

In 1938 he joined the temporary part-time staff of the British Electrical and Allied Industries Research Association, and his services were placed at the disposal of the British Standards Institution to supervise the revision of the British Standard Glossary of Terms used in Electrical Engineering. In 1941 he joined the staff of the British Standards Institution, and when the revision of the glossary was completed he agreed to remain with the Institution to assist with the preparation of other glossaries and related work.

In his latter years Roget had no hobby other than his work at the British Standards Institution. After a full day at his desk or at a committee meeting, he would often work on at the hotel in which he lived, producing documents which a less enthusiastic person would have dictated next day at the office. In this way he kept up with the work of the thirty or so committees of the Institution of which he acted as secretary, in a way which amazed his colleagues and at a pace which would have done credit to a man of half his age. With his industry he combined a quiet sense of humour and a charm of manner which endeared him to all with whom he came into contact.

Understanding between individuals and between nations depends upon the correct use of language, and much of Roget's life was devoted to the means towards such understanding. Few people possess the patience, the wide knowledge, the love of words and the clarity of expression which are so essential to this task and which were possessed in such abundance by Roget.

He leaves a son and a daughter.

J. F. STANLEY

WE regret to announce the following deaths:

Sir Charles Arden-Close, K.B.E., C.B., C.M.G., F.R.S., formerly director-general of the Ordnance Survey, on December 19, aged eighty-seven.

Mr. J. G. Robb, recently deputy engineer-in-chief of Marconi's Wireless Telegraph Co., Ltd., on December 16, aged sixty-two.

Dr. W. C. Sillar, formerly lecturer in experimental pharmacology in the University of Edinburgh, on October 23, aged eighty-eight.

NEWS and VIEWS

Division of Biochemistry, Massachusetts Institute of Technology: Prof. J. M. Buchanan

A DIVISION of Biochemistry in the Department of Biology has recently been started at the Massachusetts Institute of Technology, and Prof. John M. Buchanan, professor of physiological chemistry in the University of Pennsylvania, has been appointed the first professor and head of the Division as from July 1, 1953. The new Division will operate as an autonomous unit within the Biology Department, closely correlated with the other activities of the Department, particularly in the fields of general physiology and biophysics, and will be responsible for teaching and research in biochemistry at all levels—undergraduate, graduate and post-doctoral—in the Institute. All undergraduate students in the Biology Department will take at least one course in the Division of Biochemistry, and graduate degrees in biochemistry will be offered in connexion with the Division's research activities, which will mainly be concerned with the growth, structure and reproduction of cells. Housing for the Division will be provided on the sixth floor of the new John Thompson Dorrance Laboratories of Biology and Food Technology.

Prof. Buchanan graduated from De Pauw University, Greencastle, Ind., in 1939, and then took his M.Sc. at the University of Michigan and his Ph.D. at Harvard University. Except for two years at the Medical Nobel Institute, Stockholm, his subsequent career has been entirely at the University of Pennsylvania. He is widely known for his researches in the biosynthesis of biological compounds, particularly the purines and glycogen, and he has also made important contributions in the isolation and purification of enzymes. In 1951 Prof. Buchanan received the Eli Lilly Award in Biological Chemistry of the American Chemical Society.

Geological Society: Awards

THE Council of the Geological Society announces the following awards for 1953: *Wollaston Medal:* Prof. Erik Stensio, keeper of the Palæozoological Department in the Swedish Natural History Museum, Stockholm, for his fundamental researches on the lower vertebrates and for his remarkable techniques in palæontological research; *Murchison Medal:* Dr. F. Dixey, for his outstanding contributions to the geology of Africa and his distinguished services as director of the Colonial Geological Surveys; *Lyell Medal:* Dr. M. B. Bulman, for his important contributions to palæontology, particularly on the morphology of the Graptoloidea and to Lower Palæozoic stratigraphy; *Bigsby Medal:* Prof. K. C. Dunham, for his contributions to petrology and to the study of mineral deposits; *Wollaston Fund:* Mr. P. C. Sylvester-Bradley, for his researches on fossil Ostracoda and on Jurassic stratigraphy; *Murchison Fund:* Mr. C. D. Ovey, for his researches on fossil Foraminifera; a moiety of the *Lyell Fund* to Dr. Gilbert Wilson, for his works on structural geology, notably in Cornwall and the Highlands, and his studies of granitization and coastal geomorphology; another moiety of the *Lyell Fund* to Dr. D. A. Brown, for his contributions to the structural geology and palæontology of New Zealand, and particularly the Tertiary Polyzoa of that Dominion.

Institute of Metals: Awards

THE Council of the Institute of Metals has made the following awards: *Institute of Metals (Platinum) Medal* for 1953 to Prof. Georg Masing, of the Institut für Allgemeine Metallkunde, University of Göttingen, in recognition of his outstanding contributions in the field of metallography; *Rosenhain Medal* for 1953 to Dr. C. E. Ransley, of the Research Laboratories, British Aluminium Co., Ltd., in recognition of his outstanding experimental and theoretical work on gas-metal equilibria.

Manchester College of Technology: Jubilee Brochure

IN connexion with the jubilee of the Manchester College of Technology, an illustrated brochure has been issued (pp. 36; from the College) giving an excellent account of the origin of the College and its development since the opening of the present building in 1902. Up to 1918 the institution was known as the Municipal School of Technology; but it had already, in 1905, concluded arrangements with the Victoria University of Manchester for the institution, within the School of Technology, of the Faculty of Technology, which in its first session included 522 university students. In 1912 the School of Technology was for the first time listed with universities and university colleges in Great Britain which were in receipt of grants from the Board of Education. This was prior to the establishment of the University Grants Committee, and the Manchester Municipal School of Technology was the first municipal institution to be thus listed with university institutions. Although the brochure does not trace the earlier development to 1902 of the original Mechanics' Institute of 1824, it gives some indication of the research work carried out by the College, particularly during the two World Wars. Some account of the co-operation with industry which led first, during October 1917, to a course of lectures in scientific management and later, in 1926, to the establishment of the Department of Industrial Administration is included, and also of the post-war developments and the new buildings. Besides the thousand undergraduate university students for whom accommodation was planned for the three sessions following 1946–47, the non-university registrations reached a peak of 8,558 in 1949, of whom 7,943 were part-time students, while in 1950 more than nine hundred students were attending post-advanced classes. According to a recent estimate, the extensions originally commenced in 1938 will almost double the present accommodation. Since 1924 the number of volumes and pamphlets in the library has increased from 12,000 to 33,500, and the number of periodicals taken from 130 to 420.

Technical Education in the North of England

A PAMPHLET entitled "Technical Education in the Northern Region", giving a summary list of courses which are available in the technical, commercial and art colleges and institutes of Cumberland, Durham, the North Riding of Yorkshire, Northumberland and Westmorland, has been issued by a subcommittee of the Northern Productivity Exhibition Planning Committee, organized by the Northern Regional Board for Industry in association with the Information Division of the Treasury and others. Since 1938–39 the number of full-time students in senior and advanced courses in the region has grown from 635 to 2,152, of part-time day students from 909 to 10,552 and of evening students from 19,714 to 26,836 (1950–51), though part-time day release remains below the average for Great Britain as a whole. The Exhibition itself, which was held in the City Baths Hall, Newcastle upon Tyne, during October 30–November 6, 1952, included a technical college exhibit.

German Hydrographic Institute, Hamburg: Report for 1951

THE German Hydrographic Institute's report for 1951, its sixth year of activity (pp. 72+12 pl.; from the Institute, Hamburg 11; 1952), includes some retrospective statistics which go back to its foundation in 1946. On the whole, the Institute's work has been continued and progressively extended as in the years before, especially in the departments for nautical books and charts. Some events are mentioned which have a special importance for the Institute's further development. With regard to the work for the direct benefit of practical navigation, a committee has been established which includes representatives of all nautical and technical institutions, organizations and firms which are interested in the Institute's activities. This committee is to meet at suitable intervals in order to lodge requirements and make suggestions bearing upon the work of the Institute. As for the resumed participation in international scientific work, members of the Institute's staff took part in the meeting of the International Geophysical and Geodetic Union held in Brussels in August and September 1951, and in that of the International Council for the Exploration of the Sea held in Amsterdam in October 1951. Moreover, the Institute has been able to continue its research work in the North Sea from its vessel *Gauss*. In June 1951 a cruise was made in the Southern Bight of the North Sea for physical, chemical and plankton observations in association with contemporaneous British and Dutch fishery investigations, and a call was made at Lowestoft for discussions with British oceanographers there. During an autumn cruise in the German Bight and the Skagerrak, some methods and apparatus designed for practical marine seismology were tested, and several echograms of the deepest part of the Norwegian Trench were obtained. Following upon the Brussels and Amsterdam meetings referred to, the Institute was visited by many foreign scientific workers who had attended them.

Franklin's 'Philadelphia Experiment' on Lightning

THE May 1952 number of the *Journal of the Franklin Institute* (253, No. 5) is devoted to the subject of lightning protection in commemoration of the two hundredth anniversary of the 'Philadelphia experiment' (May 10, 1752) on the identity of laboratory and thunderstorm electrification which was proposed by Benjamin Franklin. It contains a reproduction of the first photograph of lightning, believed to have been taken by W. N. Jennings on September 2, 1882, and four articles, by B. F. J. Schonland, I. B. Cohen, K. B. McEachron and H. Norinder, respectively. The first two deal with the historical background. Prof. Schonland gives an account of the experiments and hypotheses which led Franklin to propose the famous experiment and the lightning rod as a protective device, and Prof. Cohen describes the considerable prejudice which was aroused against the introduction of lightning rods. He quotes Prof. Schonland's conclusion from his recent book that "lightning still takes a considerable toll of unprotected property in the country from which the rod came", and points out that, although lightning was given the sixth place in importance among the causes of fire during 1921 by the United States National Board of Fire Underwriters, the number of buildings with adequate lightning protection is still but a small fraction of those that require rods. Dr. McEachron, of the General Electric Co., discusses lightning protection since Franklin's day, in particular with respect to communication systems, transportation and the electrical industry. Finally, Dr. Norrinder, of the Institutet för Högspänningsforskning, University of Uppsala, deals with experimental research into lightning discharges and effects in their vicinity. Meteorological aspects and the long-distance effects—atmospherics—are not considered. Optical methods, photographic methods and high-speed cathode-ray oscillograph methods of recording lightning discharges are described, and some of the results obtained, revealing the leader stroke mechanism, are discussed and illustrated.

Handbook of the New Zealand Department of Scientific and Industrial Research

THE Department of Scientific and Industrial Research, New Zealand, has issued an illustrated and well-produced Departmental Handbook (pp. 68. Wellington: Govt. Printer, 1952) collecting much information previously only available from separate sources. An organization chart and brief account of the organization and administration of the Department is supplemented by some historical notes on its development and by maps indicating the geographical location of the units. The bulk of the Handbook consists of brief accounts of the functions and organization of the several divisions, laboratories, sections, etc., and of the incorporated research associations, including lists of staff. There is also a list of committees and their membership and of organizations in receipt of grants from the Department. The Handbook is completed with an index.

New Light on Gnetales and Ephedrales

PROF. A. J. EAMES has considered in some detail, and in the light of modern knowledge, the relationships of that much-discussed plant group, the

Gnetales—comprising *Gnetum*, *Welwitschia* and *Ephedra* (*Phytomorph.*, 2, 1, 79; 1952). These plants have long been prominent because of their very curious morphology and diverse habit, and because they appear to occupy a position intermediate between gymnosperms and angiosperms. The evidence now available points to the need for an extensive taxonomic revision. As a result, the three families are separated and raised to ordinate rank. Moreover, it is recognized that the Ephedrales have no phylogenetic relationship to the Welwitschiales and Gnetales. They are, however, closely related to the Cordaitales, both having similar appendicular ovules. *Ephedra*, in fact, is regarded as a derivative of ancient cordaite-conifer stock.

Papers from the Arcetri Astrophysical Observatory

Publication No. 67 of the Faculty of Mathematical, Physical and Natural Sciences of the University of Florence, entitled "Osservazioni e Memorie dell' Osservatorio Astrofisico di Arcetri" (pp. 141, 1952), consists of eleven papers contributed by seven authors. These papers deal with a variety of subjects: correlation coefficients between areas of sunspots and areas of calcium and bright *Hα*-flocculi; results of the examination of the mean heliographic latitude of sunspots and that of bright flocculi, from which it appears that the former are smaller than the latter; relative photometric intensities of chromospheric flares, measured monochromatically in *Hα* and *K*2·3 lines, on 258 spectroheliograms recorded during 1950 with the solar tower of Arcetri Observatory; study of the eleven-year cycle of solar prominences, without taking into consideration the distinction between those in high and low latitudes, and comparing prominences with filaments, some differences in their behaviour being detected; photometric measurements of the ghosts given by the grating of the Arcetri solar tower; relative intensities of flares and bright flocculi observed in *Hα* light on spectroheliograms taken at Meudon, and a comparison with those taken at Arcetri, etc.

The Night Sky in January

Full moon occurs on Jan. 0d. 05h. 05m., U.T., and also on Jan. 29d. 23h. 44m., and new moon on Jan. 15d. 14h. 08m. The following conjunctions with the moon take place: Jan. 9d. 09h., Saturn 8° N.; Jan. 19d. 01h., Mars 4° S.; Jan. 19d. 01h., Venus 4° S.; Jan. 23d. 02h., Jupiter 7° S. In addition to these conjunctions with the moon, Venus is in conjunction with Mars on Jan. 18d. 02h., Venus being 0·2° N. Mercury, a morning star, rises at 6h. 50m. on January 1, but later in the month it draws too close to the sun for favourable observation. Venus, an evening star, sets at 19h. 50m., 20h. 30m. and 21h. 10m. on January 1, 15 and 31, respectively, stellar magnitude averaging − 3·9 and the visible portion of the illuminated disk varying between 0·65 and 0·52. Mars is an evening star, setting about 20h. 35m. throughout the month; its stellar magnitude varies between 1·2 and 1·3. Jupiter sets at 3h. 10m., 2h. 10m. and 1h. 15m. at the beginning, middle and end of the month, respectively, its stellar magnitude averaging − 2·1. Saturn, a morning star, rises at 1h. 40m., 0h. 45m. and 23h. 45m. on January 1, 15 and 31, respectively; its stellar magnitude is about 0·9, and it lies a little north-east of α Virginis (Spica). There is only one occultation of stars brighter than magnitude 6 in January, namely, π Canc., which reappears at 6h. 18·3m., assuming that observations are made at Greenwich. A total eclipse of the moon takes place on January 29/30 and is visible in the British Isles. The circumstances of the eclipse are as follows:

Moon enters penumbra	Jan.	29d.	20h.	40·1m.
Moon enters umbra		29	21	54·1
Total eclipse begins		29	23	04·6
Middle of eclipse		29	23	47·3
Total eclipse ends		30	00	29·9
Moon leaves umbra		30	01	40·4
Moon leaves penumbra		30	01	54·5

The earth is at perihelion on January 2.

Announcements

Prof. J. F. Baker, professor of mechanical sciences and head of the Department of Engineering, University of Cambridge, has been awarded the Ewing Gold Medal of the Institution of Civil Engineers, in recognition of his contributions to engineering research.

In reply to a question in the House of Commons, the Minister of Works stated that the planning of the Government Science Centre has had to be deferred in view of the need for economy. When the economic situation improves, it is hoped to lease a site on the South Bank immediately below Waterloo Bridge.

The annual exhibition of the Television Society, dealing with television engineering or production or with the production of television programmes, will be held during January 23–24, 1953, at 155 Charing Cross Road, London, W.C.2, by invitation of the Edison Swan Electric Co., Ltd. The exhibition will be open as follows: January 23, 6–9.30 p.m., members and friends; January 24, 10.30 a.m.–6 p.m., members. Public admission is by invitation card, obtainable from members of the Society, patron members or from the lecture secretary, G. T. Clack, 43 Mandeville House, Worsopp Drive, London, S.W.4.

A symposium on anticholinesterases, arranged jointly by the British Pharmacological Society and the Fine Chemicals Group of the Society of Chemical Industry, will be held during March 27–28, 1953, at the Wellcome Research Institution, Euston Road, London, N.W.1. The symposium will be in four sections: chemical features which confer inhibition; mode of action *in vitro*; mode of action *in vivo* (acute effects); mode of action *in vivo* (chronic effects). Further information can be obtained from the honorary secretary of the British Pharmacological Society, Mr. George Brownlee, at the Physiology Department, King's College, Strand, London, W.C.2.

An International Congress on Electroacoustics will be held in the Netherlands during June 16–24, 1953, under the auspices of the International Commission on Acoustics of the International Union of Pure and Applied Physics. Lectures and invited short contributions will be read covering the following sections: (1) sound recording, (2) public-address systems, (3) acoustic measurements, (4) hearing-aids and audiometers, (5) electroacoustics in ultrasonics, and (6) electroacoustics applied to musical instruments. These will be followed by a symposium on the sound insulation of lightweight structures. Further details can be obtained from the secretary, Dr. P. A. de Lange, Mijnbouwplein 11, Delft.

The lectures delivered at the vacation school on the "Insulation of Electrical Equipment" held at the Imperial College, London, in September (see *Nature*, Dec. 13, p. 1006) are being published in book form by Chapman and Hall, Ltd., 37 Essex Street, London, W.C.2, under the editorship of Prof. Willis Jackson.

UNIVERSITY COLLEGE, IBADAN

FORMAL OPENING

ON November 17, Marshal of the Royal Air Force Lord Tedder, Chancellor of the University of Cambridge, formally opened the buildings of what in a few years time will be the University of Nigeria. This was the fourth anniversary of the ceremony when the then Secretary of State for the Colonies, Mr. Arthur Creech Jones, cut the first sod and inaugurated the building programme; the Soil Science Laboratory of the Department of Agriculture appropriately stands on the spot. Less than six years ago a commission appointed by the Inter-University Council for Higher Education in the Colonies, under the chairmanship of Sir William Hamilton Fyfe, selected the site, which was then a tract of unsurveyed and almost impenetrable bush.

The capital cost of the new buildings has been provided by a grant from the British Exchequer under the Colonial Development and Welfare Act. The sum of £1,500,000 was set aside in 1947, and on November 17 Sir Christopher Cox, educational adviser at the Colonial Office, announced, on behalf of the Secretary of State, that a further £200,000 had been added, to offset increased prices and to allow the whole of the first phase of the scheme to be completed. The whole of the recurrent costs of the College, which now amount to about £400,000 per annum, come from Nigerian sources, either as a direct subvention from the Government or as interest from endowments from the same source or from the marketing boards (for example, the Cocoa Marketing Board has endowed the School of Agriculture to the extent of £1,000,000).

The site of nearly 3,000 acres was acquired for the College by the Nigerian Government and lies some three miles north of Ibadan. Ibadan is the largest town in tropical Africa, with an estimated population of half a million inhabitants, mostly Yoruba, but with substantial numbers of settlers from other parts of Nigeria, and a few hundred European, Syrian, Indian and other expatriates.

The site, as well as containing the main academic buildings, houses more than a hundred members of the academic staff, and several hundred junior employees. The greater part of the 3,000 acres will, however, be developed as experimental farms by the Department of Agriculture.

The buildings, designed by Mr. Maxwell Fry and Miss Jane Drew, comprise residential accommodation for nearly six hundred student in halls of residence and teaching blocks for the departments in the Faculty of Arts, including a theatre, library, administration building and an assembly hall; this last is a gift from the United Africa Company, and is to be called Trenchard Hall, after Lord Trenchard, chairman of the Company, who during 1903–10 saw service with the Army in Nigeria.

There are at this stage four halls of residence, in each of which the plan follows the general recommendations of the committee set up by the vice-chancellors and principals of universities in Britain. Each undergraduate has a separate study-bedroom, and there are a communal dining hall and recreation rooms in each hall of about 150 students. The buildings have been planned for tropical conditions, and although they are built around courtyards, most of the residential blocks run east and west to avoid direct sun shining into the rooms. Each room has through ventilation, and each study-bedroom a private veranda.

The laboratories, for the Departments of Chemistry, Physics, Botany and Zoology in the Faculty of Science, for Agriculture, for Anatomy, Physiology and Pharmacology in the Faculty of Medicine, have been planned for construction with the maximum economy, and so as to be easily adapted and converted to meet changing needs. These buildings have been designed by Mr. J. Hoskins, of the College staff, collaborating where necessary with the architects to ensure that the façade conforms with the general layout plan. These laboratories are of one story only (this is much cheaper to construct under Nigerian conditions than loftier buildings), and they are planned to be able to house a much larger number of students and of staff than will immediately be necessary. Thus the Departments both of Chemistry and of Physics have each about 18,000 sq. ft. of laboratory space.

The buildings now constructed are intended to house the College in the first phase of its development; but the site has been planned so that a great expansion is possible. More halls of residence are likely to be the first necessity, and sites for at least six more are scheduled. The teaching departments can be easily extended to take several thousand students,

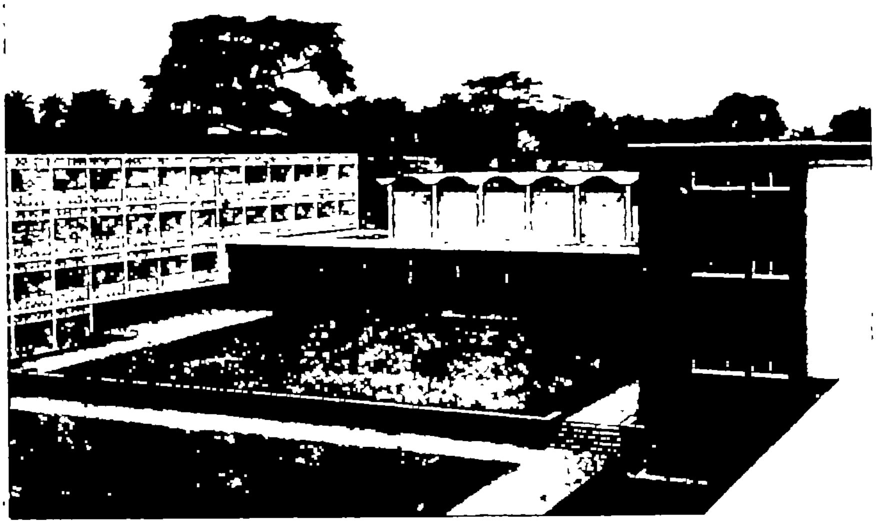

Fig. 1. Part of the court inside a hall of residence; students' study-bedrooms on the left, dining hall centre

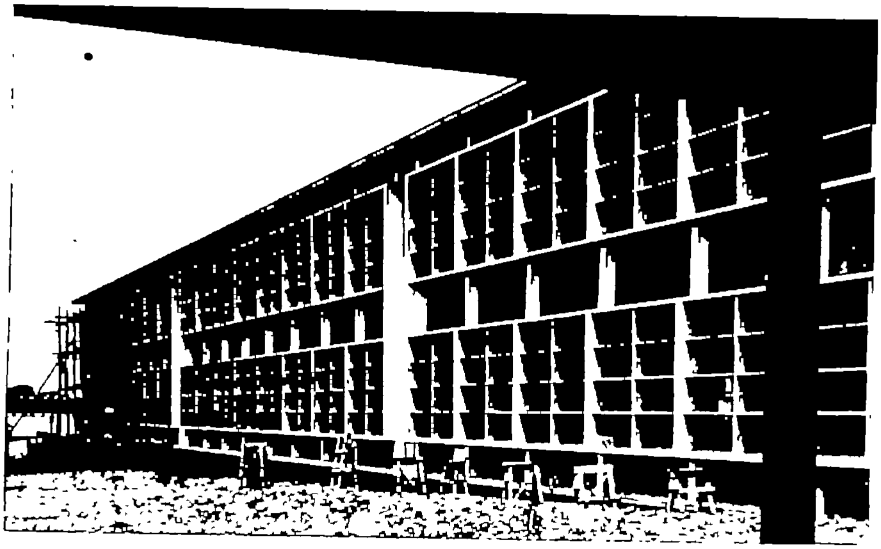

Fig. 2. North wing of the arts building, containing Departments of Geography, Mathematics and Phonetics

though those at present responsible for planning the College think that when the undergraduate community reaches about 2,500 a start should be made with a second Nigerian university in another part of the territory.

The College has already been working for more than four years in temporary buildings in a converted military hospital. The preclinical and agricultural students have now moved into their permanent quarters; but the Faculties of Arts and Science will not be able to move for some months. There are at present in residence in Ibadan nearly 400 undergraduates, and an academic staff of more than a hundred.

Ibadan students work for degrees of the University of London. The College is in a "special relationship" with the University; this means that, while academic standards are guaranteed, there is some latitude in adapting the syllabus to meet local needs. Thus in the biological sciences, geography and history, for example, special courses have been evolved. The preparation of these syllabuses, which will develop as the appropriate research work into African problems progresses, gives useful experience which will be of value when the College becomes an independent university.

The whole course leading to general or honours degrees in a wide range of arts and science subjects, and in agriculture, can be completed in Ibadan. In medicine, teaching at present only extends to the end of the preclinical course; for clinical studies, students proceed overseas, but work is proceeding on the Teaching Hospital (for which the Nigerian Government has granted £2,250,000) and soon it is hoped that the final London M.B., B.S., may be taken in Ibadan. At present there are no hospitals in Nigeria suitable to obtain recognition for teaching of the appropriate standards.

Nigeria, with a population estimated at not far short of 30,000,000, will require far more graduates than the College can at present produce, but the size of the entry is at the moment largely dependent on the production of suitable freshmen by the secondary schools. So far, few suitable candidates have failed to secure entry. An attempt is being made to maintain a proper balance of the different faculties, and notwithstanding the obvious demand for well-qualified scientists and technicians, arts subjects are by no means neglected.

Academic work in the tropics often suffers from the lack of library facilities. The library at Ibadan already contains more than 70,000 volumes, and receives about a thousand current periodicals. The new building will take, without extension, more than a quarter of a million volumes. Microfilms are extensively used, being frequently flown out from Europe for the urgent use of readers, and the library can make its own microfilms and photostat copies for the use of readers elsewhere. Many back-numbers of otherwise unobtainable scientific journals are available on microcards; Ibadan was the first Commonwealth library to use this technique.

Everyone at Ibadan realizes that the future standing of the University College will depend on the quality of the original work carried out there, both by the staff and by visiting investigators using the College's facilities. All departments are planned not only to allow for an increase in student numbers, but also to accommodate visitors from overseas. Several such workers have spent considerable periods at Ibadan. Fulbright Scholars from the United States have, for example, studied primate physiology, poultry husbandry, indigenous songs and other cultural problems. A Medical Research Council team investigated vegetable precursors of cortisone. But the main research must always be done by the College itself, and a good start has been made in all faculties; in medicine, where no clinical teaching will take place for a few years, research will largely determine the details of the courses which will eventually be given.

At this stage it is impossible to foretell the exact future development of the College. This depends only in part on the College itself. The political situation in Nigeria is changing rapidly, and it is the more

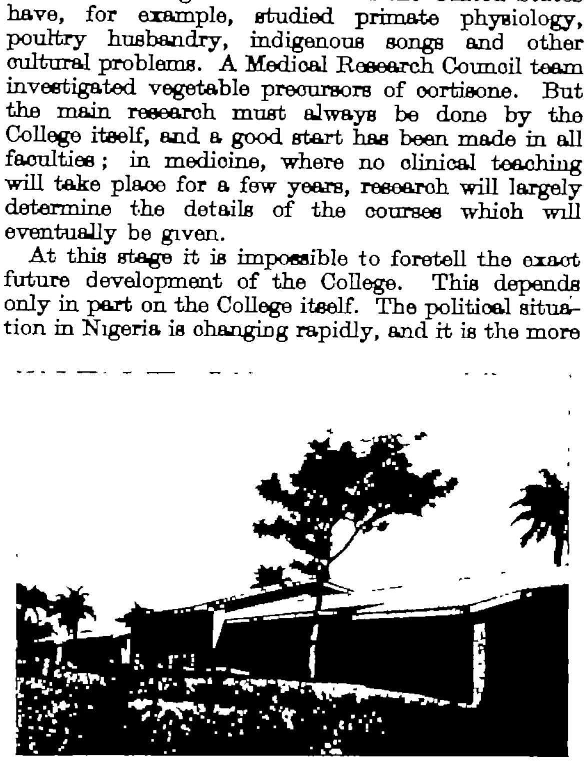

Fig. 3. Elementary chemistry laboratory; the Department of Chemistry includes three similar parallel buildings

moderate politicians who speak of "Dominion status in 1956". The College is a fully autonomous institution, and so far there have been few attempts, save by the less responsible organs of the popular press, to interfere with this autonomy. Nevertheless, until the College and its standards are firmly established the danger of outside political pressure will remain, and will impose an added strain on those responsible for the well-being of an institution on which the future of Nigeria itself depends so greatly.

INTERNATIONAL FEDERATION FOR DOCUMENTATION

CONFERENCE IN COPENHAGEN

THE International Federation for Documentation held one of its 'restricted' conferences in Copenhagen during September 28–October 4, which was attended by representatives of some sixteen countries. These conferences consist of a number of meetings of the council and of the active specialist committees of the Federation. Among the committees which met on this occasion were those on universal classification, mechanical selection, technical means of documentation, abstracting, training, and information services. Meetings were also held between members of the staff of the United Nations Educational, Scientific and Cultural Organization and representatives of the council of the International Federation for Documentation, the International Federation of Library Associations and other international bodies concerned with documentation, archives and librarianship. As a step towards closer collaboration, it was agreed that both the International Federation for Documentation and the International Federation of Library Associations should become members of the other's organization and that the next conferences of the two bodies should take place simultaneously in Vienna in 1953. It was also agreed with the representatives of Unesco that a joint consultation committee of international non-governmental organizations in the field of librarianship, documentation and archives be established, and that this committee should arrange the next world conference on these subjects to be held in 1954 or 1955.

One of the main items discussed by the council of the Federation was the report of its committee on reorganization, which was set up at the end of the conference held in Rome in 1951. This report, which was accepted after minor modification, restated the aims of the Federation in terms suitable for the present; in particular, it made clear that such a body should restrict its activities to those which are truly international in character, leaving studies of a more general nature to its national constituent bodies. Similarly, it was agreed that international technical studies should not necessarily be carried out by the general secretariat but allocated to appropriate national members who would undertake them for the benefit of the Federation as a whole. It also recommended that international specialist bodies should be accepted as members of the Federation in addition to the national co-operating bodies (Aslib in the case of Great Britain). It was recognized that, with the increased amount of research undertaken, especially in the pure and applied sciences, and the consequent volume of publication, special problems of documentation are arising in many scientific and technical fields. As a result, a number of specialist international bodies have already been established, such as the International Council on Building Documentation which was meeting at Copenhagen at the same time as the International Federation for Documentation. The Federation felt itself to be in a position to give advice to international bodies for specialized topics, such as the various international scientific unions, on documentary aspects of their work, and decided to create facilities for such bodies to join the Federation and participate fully in its work.

Among the technical matters agreed as appropriate to the programme of the Federation for 1953, priority was given to the proposals for a guide to centres for microfilm and photocopying services, and centres for international loans and translation services; the production of manuals for instruction in documentation; a directory of the effective members of the Federation, with a description of their activities; a study of auxiliary publications, including 'unpublished' reports of scientific work; a study of costing and economics in the preparation and sale of photocopies; and a manual of documentary reproduction.

This conference, with its wide scope of technical interest, demonstrated clearly the need for improved services of documentation and information as well as the interest of scientific and technological workers in problems resulting from the mounting pressure of publication. Although a number of international organizations are operative in this and neighbouring fields, the International Federation of Documentation, in encouraging co-operation with other bodies while at the same time improving its own organization and procedures, is showing real leadership and finding a useful continuing function.

ADVISORY COMMITTEE ON ARID ZONE RESEARCH

MEETING IN LONDON

THE Advisory Committee on Arid Zone Research set up by the United Nations Educational, Scientific and Cultural Organization held its fourth meeting in the Royal Society's rooms, Burlington House, London, during September 29–October 1. Following its former policy, the Committee's recommendations were concerned to a large extent with the dissemination and exchange of information by means of reports and symposia. Reports have already been obtained and circulated on arid zone hydrology, on plant ecology, on the climatic history of arid regions and on the utilization of salt water. A successful symposium on arid zone hydrology organized jointly by Unesco and the Turkish Government was held in Ankara last April. The Committee recommended that qualified experts be commissioned to prepare reports reviewing research on energy sources, including wind and solar energy and their utilization in arid and semi-arid regions, and also on the general characteristics of arid zone soils and their modification. It also recommended that a survey of current research in the field of arid zone plant ecology be prepared. The symposium planned to be held in 1953 will deal with this field of plant ecology in arid regions, and the Committee considered its programme and plans for holding it in a Latin-American country in the autumn.

Plans were also discussed for the production of a handbook to assist those confronted with the task of collecting basic data required before schemes can be prepared to develop an arid or semi-arid area. Such a handbook would aim at serving two purposes. It would first direct the attention of persons concerned with organizing development to the various and interrelated fields in which data are needed before satisfactory plans for such development can be made. Secondly, it should give information as to the best methods of collecting and presenting basic data in a form that supplies the information needed for their practical application.

A scheme is now in operation in which certain institutions carrying out research relating to arid zone problems may be designated as suitable for the exchange of personnel and information and for the reception of visiting scientific workers. A number of applications for designation under this scheme were considered by the Committee, which recommended that the following institutions be added to those already designated at earlier meetings:

Commonwealth Research Station (Murray Irrigation Areas), Merbein, Victoria.
Division of Plant Industry (C.S.I.R.O.), Black Mountain, Canberra.
Irrigation Research Station (C.S.I.R.O.), Private Mail Bag, Griffith 58, New South Wales.
Katherine Research Station, Katherine, Northern Territory.
National Field Station, "Gilruth Plains", Cunnamulla, Queensland.
Information on Regional Pastoral Laboratory, Deniliquin, Box 26, P.O., New South Wales.
Laboratorium voor Grondmechanica, Oostplantsoen 25, Delft.
Waterloopkundig Laboratorium (Hydraulic Laboratory), Raam 61, Delft.
Amarillo Conservation Experiment Station, Box 2160, Amarillo, Texas.
Department of Geology, University of Southern California, 3518 University Avenue, Los Angeles 7, California.
Inter-Mountain Forest and Range Experiment Station, U.S. Forest Service Building, Ogden, Utah.
Information on Reclamation Engineering Centre, Denver, Colorado.
South-western Forest and Range Experiment Station, Tucson, Arizona.
University of Arizona, Tucson, Arizona.
University of California Citrus Experiment Station, Riverside, California.

Particulars of these institutions and of the facilities available at each can be obtained from Unesco (19 Avenue Kléber, Paris 16e). The Committee also recommended that member States be reminded of this scheme and be supplied with a full list of institutions at present associated under it.

As a result of an earlier recommendation by the Committee, a survey has been conducted by Unesco of institutions engaged in research on arid zone problems, and the Committee recommended that the information thus collected should be made use of to compile a directory of institutions engaged in arid zone research.

On the research side the Committee recommended that assistance be given to the following projects. (1) A project proposed by the Institut Français d'Afrique Noire to study the effects on plant cover of natural factors, mainly climatic, and of human intervention such as grazing, trampling and wood cutting. Data on this subject are much needed, especially since they bear on the deterioration of natural pastures. (2) A project proposed by Dr. F. W. Went, of the Earhart Plant Research Laboratory, California Institute of Technology, to study the role of dew in plant growth in arid regions. (3) A project proposed by Dr. K. Smidt Nielsen, of Duke University, North Carolina, to study the physiology of the camel and of other desert mammals. This work would extend that already carried out by Dr. and Mrs. Smidt Nielsen on the physiological mechanisms which enable certain desert rodents to live on dry food without drinking water. (4) A project proposed by Prof. L. Picard, Geological Institute, Jerusalem, Israel, to investigate the climatic changes that have taken place during the Quaternary in the arid and semi-arid region of the south-east Mediterranean, initially by means of a study of the peat deposits of northern Galilee.

EUROPEAN COUNCIL FOR NUCLEAR RESEARCH

SESSION IN AMSTERDAM

THE third session of the European Council for Nuclear Research was presided over by Prof. P. Scherrer when it met at the Academy of Sciences, Amsterdam, during October 4–6. The main work before the Council was to consider the offers which had been made by various member States for the site of the proposed laboratory, to hear reports of progress made by its four study groups, and to consider a report from its secretary-general, Prof. E. Amaldi, on the organization and financial implications of future European co-operation in nuclear research. Last June the Council sponsored a scientific conference at Copenhagen to promote a broad exchange of views upon the problems of nuclear research which could be most profitably dealt with by international co-operation. As a result of this conference, it has been decided that the study of mesons and the other new particles which have recently been found in the cosmic rays should be developed by international co-operation, and by the construction of high-energy machines in a suitable centre so that these particles might be created artificially. Four working-groups were formed by the Council to carry out the following respective tasks: the first to design a 600-MeV. synchrocyclotron; the second to design a proton synchrotron of not less than 10 GeV. (10^{10} eV.) energy; the third to study theoretical and experimental developments having a bearing on the aims of the Council and to promote other forms of European co-operation in nuclear physics; and the fourth to explore the organization and structure of a suitable laboratory.

Rapid progress with the design study of the 600-MeV. synchrocyclotron was reported by Prof. C. J. Bakker. The main features of the magnet design have been settled, and also the layout of the vacuum chamber and radio-frequency system. At one stage it had been intended to use a rotary condenser to provide the necessary radio-frequency tuning, but as a result of a recent visit to the Radiation Laboratory of the University of California, the use of a vibrating-reed method of tuning is now being studied. The general design has advanced to the stage where it is necessary to start considering the manufacture of the various components.

Prof. O. Dahl reported that, since the last Council meeting in Copenhagen in June, an event of considerable scientific interest has occurred which has profoundly affected the work of the Proton Synchrotron Group. Drs. E. D. Courant, M. S. Livingston and H. S. Snyder, of the Brookhaven National Laboratory, have proposed a new focusing principle applicable to a high-energy proton synchrotron.

This principle splits the magnetic guiding field into sectors that are alternately strongly focusing and defocusing. The net effect of a combination of sectors in this way is a strongly focusing action such that any oscillations about the equilibrium orbit induced in the motions of the particles are kept small in amplitude. This is of outstanding importance since, for a given energy, the particles may be constrained within an annulus of much smaller dimensions than is the case with a machine of conventional design. Preliminary study has suggested that it should be quite practical to design a machine for 30 GeV. in which the energy to be stored in the magnetic field is not more than that required for the present 3-GeV. machine at Brookhaven. The work of the Proton Synchrotron Group has been changed to take advantage of this new idea. The Council expressed its approval of this.

One part of the work of the Council's Group directed by Prof. Niels Bohr is to promote forms of European co-operation in nuclear physics other than the creation of the laboratory. Sweden has offered to the Council facilities on the 200-MeV. cyclotron which is now working at the University of Uppsala, and Prof. Bohr reported that he has arranged on the Council's behalf for two or three young nuclear physicists from other European countries to take part in work with the machine. Great Britain also has offered facilities on the 400-MeV. cyclotron now nearing completion at the University of Liverpool, and this, too, has been accepted. Prof. Bohr also described an experiment carried out at the Institute of Theoretical Physics, Copenhagen, by Prof. J. C. Jakobsen, which was of interest to the Council because it illustrated the new focusing principle proposed for proton synchrotrons. Four sections of a magnet were used, being constructed so as to provide focusing and defocusing fields in alternate sections. Particles were injected from an alpha-particle source into these fields, and it has been shown by the use of a photographic plate that they were brought to a focus at the end of the fourth section. This experiment has provided confirmation of the first-order theory of the new focusing method. While it was recognized that the experiment still left unanswered important questions about particle stability under practical operating conditions, the Council expressed its appreciation of the work.

In a report by Dr. I. L. Kowarski, it was stated that the main work of the Laboratory Group since the Council's last meeting has been concerned with obtaining the relevant technical information about the sites offered for the laboratory and with the preparation of a draft convention for the building stage. Four member States had made formal applications to the Council to have the laboratory built in their territory, namely, France, Denmark, Holland and Switzerland ; each country had supplied detailed information about its site and had been invited to make the case for it to the Council. From the information given, it appeared that any of the four sites would be satisfactory on purely technical grounds. It was generally recognized that the choice would also take into account other considerations, such as the balance between international common good, plus the national benefit from it, on one side, and the necessary sacrifice of national resources, on the other. Competition between each of the four member States to have the laboratory within its territory was keen, but the subject was debated in a courteous atmosphere, and when all but Switzerland had withdrawn their offers, however reluctantly Geneva was unanimously chosen as the site for the future laboratories.

Since the Council had decided at its second meeting to give support to cosmic-ray research, the secretary-general reported to it the results of an international expedition which had been independently organized and operated in the Mediterranean area to carry out research in the high atmosphere using balloons. A total of thirteen balloons has been launched, and 1,300 c.c. of emulsion exposed to radiation at 70,000 ft. for an average time of 6½ hours has been recovered. This is approximately ten times more emulsion than has previously been exposed. It was considered that, besides providing a considerable amount of material for research work, the expedition has been very useful for improving the technique of balloon launching.

In his draft of an interim report for the governments of member States, the secretary-general outlined how the Council came into being, its present stage of development and its plans for the future. At the present time studies concerning the equipment and organization of a laboratory are in full progress. It is hoped that by the spring of 1953 these studies will have advanced sufficiently to allow member States to take final decisions regarding the construction of an international nuclear research laboratory, and the organization of other forms of co-operation in nuclear research. It is estimated that the next stage of development will last seven years and cost a total of 27 million dollars, after which the estimated annual running cost of the laboratory would be a maximum of 1½ million dollars. Very preliminary consideration was given to questions of organization which will arise in the third stage and to the form of the convention which will set out the constitution of the organization. This report is to be studied again by the Council before it is submitted to the governments.

TERCENTENARY OF THE LEOPOLDINA ACADEMY, SCHWEINFURT

THE tercentenary of the foundation of the Leopoldina Academy in Schweinfurt, Bavaria, in the West Zone of Germany, was commemorated during July 13–15 under the auspices of the civic authorities and Historical Society of the town. This was in the nature of a *Nachfeier* to the main celebrations at Halle in the East Zone of Germany (see *Nature*, April 5, p. 576), at which the Schweinfurt delegate was Dr. Josef Helfrich. Prior to the zonal split, the late president of the Academy, Prof. Emil Abderhalden, who died in Zurich in 1950, had hoped for the tercentenary celebration to be held in Schweinfurt.

The Senate of the Academy at Halle, under its newly elected president, Prof. Otto Schluter, and new senior vice-president, Prof. Heinrich Brandt, was represented by the secretary, Prof. Rudolph Zaunick, of Dresden (East Zone), who placed a wreath on the grave of the founder, Dr. Johann Lorenz Bausch (1605–65), reported on the present activity and projects of the Academy, and held a business meeting of members. The Martin-Luther University of Halle was represented by the rector, Prof. Rudolf Agricola. Prof. Michele Gortani brought greetings from the University and Academy of Bologna. A telegram was read from the veteran member, (the late) Sven Hedin, the Swedish explorer.

Prof. Zaunick spoke at the opening session on "Idee, Form und Inhalt der Akademie in der Antike". He showed how the modern idea of a scientific academy goes back not to the Ακαδημεια of Plato, which excluded and explicitly ridiculed experimentation, but to Ptolemy's Μουσειον.

At the scientific session, Prof. Wilhelm Lorey, of Frankfurt, spoke on "Persönliche Erinnerungen an Mathematiker unter den einstigen Akademie-Mitglieder". The Leopoldina Academy, which started as a medical society, took in no pure mathematicians as such until 1876. But some members, such as Werneburg, Goethe's contemporary, like him hostile to Newton's colour theory, and a fanatical protagonist of the duodecimal system, had started life as mathematicians, and many more, like Goethe, recognized the great educative value of mathematics. A pupil of Georg Cantor at Halle and of Felix Klein at Göttingen, Prof. Lorey recalled that he was often the sole audience at Cantor's lectures; and as one of the very few surviving contemporaries of Grace Chisholm (afterwards Mrs. W. H. Young) at Klein's seminar, he told the story behind her 'unforgettable' first appearance in the famous armchair at Klein's house. An enlightened Prussian Minister for Education, who thought mathematics the best subject to use as a guinea pig in testing whether women could or should be admitted to the universities, but wished to create no precedent for German women, entrusted to Klein the task of making suitable inquiries on his professional travels abroad. Grace Chisholm came from Cambridge and Mary Winston from the United States, and by their success opened up university careers to German women. The talk was illustrated by lantern-slide portraits of many eminent mathematicians whom the speaker had known personally.

Dr. Steck, of Nuremberg, under the title "Albrecht Dürer als Mathematiker und Kunsthistoriker", claimed that Durer had made a thorough study of mathematics and expressed life-long ideas on the unity of beauty and truth in his last three written works, "Unterweisung der Messung . . ." (1525), "Befestigungslehre" (1527) and "Proportionslehre", published posthumously (1528).

Prof. Hans Gallwitz, director of the Geological Institute at Halle, gave a talk of the greatest interest on "Ausgrabungen von Wirbeltieren und Insekten in der Eozänen Braunkohle". Unique palæontological discoveries have been made in the open-cast coal-mines in the Geiselthal near Halle. Excavations started by J. Weigelt in 1928 have only since the Second World War been successfully resumed, and praise is due to the mine-management and workers for their consistent co-operation. A film taken on the spot showed how specimens are detached and treated for preservation. The finds are unusually complete: not only whole skeletons, but also some skin, muscle and other soft-tissue remains are found, and even colours have been preserved in some green plant leaves and iridescent beetles. It is clear that the rate of sedimentation was rapid enough to prevent the attack of organic substances by atmospheric oxygen. Moreover, large desert tracts surrounded the district, isolating it and its inhabitants. The coal strata have an extensive surface area and attain a thickness of up to 100 m. on the southern rim. Tectonic movements, and particularly subsidence due to salt-leaching in the underlying Permian, can be clearly traced in the profiles; the formation of deep water-holes produced by the aforementioned process was particularly favourable to the concentration of specimens; others are found closely scattered over certain areas, called *Leichenfelder*, which were subject to recurrent flooding and which must have been formed as the result of periodically recurrent catastrophes.

The period, about forty million years ago, to which the finds belong lies near the beginning of the mass-development of the mammalian order. Plant remains clearly indicate a tropical and sub-tropical climate, and a dual rainy season is evidenced both by the two-fold lamination in the coal profile and by the otoliths of fish. In fishes and frogs, the shape of cutaneous pigment-carriers as seen under the microscope points to asphyxiation. Minute specimens of insect larvæ, pollen grains of the order of 10^{-6} gm. in weight, and even bacteria in the tracheæ of insects have been discovered. Among the finds are giant serpents, long-legged alligators, crocodiles with partially incubated eggs, a mammal transitional between insectivores and prosimians (with both hairs and spines), and one of the early prototypes of the horse, one foot high, with three toes on the hind-feet and four on the fore-feet.

Prof. H. Burgeff, of Würzburg, fresh from a visit to the United States, spoke on "Samenkeimung, Entwicklung und Kultur deutscher Orchideen", elucidating by diagrams and lantern-slides his method of cultivation in a double flower-pot, the seeds being planted individually in a net or weft of fungus-threads. The method has succeeded for all indigenous orchids, after guarding against the danger of destruction by mice, whereas the usual method has always failed except for the Platanthera.

Several speakers, notably Prof. Hämel, of the two-hundred year old Bavarian Academy of Sciences, Prof. D. Ackermann, of Würzburg, and Dr. F. Gademann, of Schweinfurt, did justice to the life-history and supra-national aims of the Leopoldina and of its foundation members—Brausch, Fehr, Metzger and Wohlfarth. These last-named were the first to put into practice the precepts, set out in the "New Atlantis" by Francis Bacon, for a scientific academy such as every principal city of Europe was soon to possess (London 1662, Paris 1666, Berlin 1711, Madrid 1713, St. Petersburg 1725, etc.). It is remarkable that this occurred in a small market-town, with a strong industrial background, in times of disruption rather like our own. A quotation that mystified some of the audience was from the curious charter that Kaiser Leopold I granted the Academy in 1687, when also it acquired its full name, conferring, as one of the normal privileges due to the Court rank bestowed on the president by the charter, the right to "legitimize illegitimate children" and to "declare dishonourable persons honourable".

Schweinfurt has preserved intact the fine library of more than a thousand volumes left to it by Dr. Bausch, chiefly on medical and botanical subjects; a large part was on view, together with works by other local Academy members—notably that on Japan by Philipp Franz von Siebold (1832), and with it his "Life" by the Japanese, Prof. Shuzo Kuro (Tokyo, 1926), the largest biography of a European ever written by an Asiatic.

An impersonation of the native poet Friedrich Rückert (1788–1866), a Haydn serenade in the courtyard of Mainberg Castle and a visit to the exhibition of medieval Franconian church art at

Würzburg Castle—the most striking feature of which was a large collection of the sculptures of Tilman Riemenschneider (1460–1531)—were the main social items in the proceedings, which were essentially informal. As in the case of the Halle celebrations, detailed reports will be published in the *Nova Acta Leopoldina*, including a full account of Prof. Gallwitz's researches. But, as yet, no copies of the current year's issue have reached the British bodies who were recipients before the War (and whose publications have been received up to date by the Academy), although at the time of the Halle meeting it was hoped to make up the deficiency forthwith.

R. C. H. Young

FARM WATER SUPPLIES

On October 21, under the auspices of the Society for Applied Bacteriology, a series of papers were read on various aspects of "Farm Water Supplies". The introductory paper was given by Mr. G. T. Morgan (Ministry of Agriculture and Fisheries), who at the outset emphasized the great importance of cleanliness in milk production and the significance of water supplies in this connexion. Of the 158,000 milk producers in Great Britain, 40 per cent own less than ten cows, and a large proportion still have inadequate and unsatisfactory water supplies to meet the estimated daily requirement of some 30–35 gallons per animal. With so many small units it is difficult to effect immediate improvements, particularly when so many of them have been producing satisfactory milk for many years. Information is being collected continuously, supplies are checked, and advice is given for improving their quality; reasonable time being allowed to correct faults and to effect the desired improvements.

Sir William Savage (Taunton), the eminent authority on public health matters, emphasized the need for a practical approach to the problem, since it is clear that piped supplies for all agricultural purposes are not possible, first on economic grounds and, secondly, because there is not sufficient water available. The quantities and qualities required must, therefore, be related to their uses. On only rare occasions have water supplies been incriminated in epidemics of bacterial infection, and in these cases the *Salmonella* and enteric organisms have been involved. Moreover, for most dairying purposes, the standards of water supplies need not be as high as those for general domestic supplies. Well and stream waters are quite satisfactory for animal drinking and for byre washing. Pure supplies are essential for washing all surfaces which come into direct contact with the milk. Sir William was sceptical of chemical disinfection, since this is usually carried out by unskilled farm hands.

Mr. W. A. Cuthbert (Leeds) said that 97 per cent of farm water supplies are from wells, usually shallow ones, or from springs. By means of a series of lantern slides he illustrated the unsatisfactory nature of many such wells and the difficulties of tracing the real sources of some of the springs. Infection in these waters are mainly found to be due to human pollution, which can be eliminated by appropriate protective measures, although these often involve reconstruction. Chlorination should also be employed, but this cannot be relied upon entirely to render a bad water safe. In farm water supplies, the counts of *Bact. coli* and *coli-aerogenes* groups vary independently, so that differentiation of fæcal and non-fæcal organisms is of little value for diagnostic purposes. Topographical examination of all supplies is essential and should be considered along with bacteriological findings before expressing judgment on any supply. Numerical standards for bacterial content are in themselves of no value in assessing farm water supplies because of the considerable seasonal variations encountered. Investigation has shown that factors responsible for this variation include soil temperature and, to a less extent, rainfall.

Dr. J. H. McCoy (Hull), considering the significance of polluted farm water supplies in relation to human infection, said that standard bacteriological tests cannot of themselves guarantee the non-pathogenicity of any supply. Topographical examination is a first essential to eliminate obvious faults. Epidemics of milk-borne enteric infections are traceable mainly to carriers, but a small number is undoubtedly attributed to the water supply, for example, the Croydon epidemic of 1937. Dr. McCoy also directed attention to organisms likely to cause spoilage in dairy products, such as lipolytic and proteolytic bacteria in cheeses, but said that these should not be present in large numbers in properly handled milks. Mr. T. C. Ketchen (Ministry of Agriculture and Fisheries), again emphasizing the practical and financial aspects, described in detail several ways in which the design and maintenance of farm water systems could be improved. Examples were given of how these could be effected by fencing off springs and wells from animal contact, by substituting bore-holes for shallow wells, by re-directing and piping flows from springs, or by proper walling and fencing of well-mouths.

The discussion was opened by Dr. Windle Taylor, who emphasized the importance of chemical tests on waters, and expanded further the significance of the *Bact. coli/coliform* ratio, stating that fæcal *Bact. coli* appears to survive much longer in water than was originally thought.

INTERNATIONAL SANITARY REGULATIONS

For more than a hundred years the progressive nations of the world have endeavoured to arrange a uniform sanitary code to govern international traffic and to utilize the best preventive measures against the importation of infectious diseases, especially cholera, plague and yellow fever. Important work to this end was done by the Pan-American Sanitary Bureau, the Office International d'Hygiène Publique, and the Health Organization of the League of Nations[1]. The development of air travel led to the International Sanitary Convention for Aerial Navigation, afterwards modified in 1944, like the convention of 1926 for maritime traffic.

During the first half of the present century there were as many as thirteen conventions or diplomatic arrangements relating to health control measures to be taken at frontiers. None of these conventions completely superseded all its predecessors, nor were all the States parties to these arrangements, some participating in certain of them and not in others. This disunity caused trouble and confusion in international traffic. Further defects were the delay in ratification, which prevented the application of the agreed measures rapidly and simultaneously; and the difficulty of revising them expeditiously in the light of scientific and technical progress, experience gained and new epidemiological knowledge.

The United Nations World Health Organization was established in 1946, and in its constitution was given authority to adopt international sanitary regulations. Without delay, the Interim Commission of the Organization appointed expert committees to prepare a revision of existing sanitary conventions. They studied such questions as the sanitary control of the Mecca Pilgrimage, modern advances in epidemiology and methods of preventing transmission of disease by insect vectors. The technical documentation thus produced enabled the Expert Committee on International Epidemiology and Quarantine, with the help of its legal sub-committee, to prepare preliminary draft international sanitary regulations. In April–May 1951 these regulations were considered by the special committee appointed by the Third World Health Assembly at thirty-six plenary meetings held in the Palais des Nations, Geneva, under the chairmanship of Dr. M. T. Morgan (Great Britain). After receiving comments and suggestions from the delegates of the member States, a final draft was prepared which the special committee submitted to the Fourth World Health Assembly. The text of the Regulations was adopted unanimously on May 25, 1951, by the representatives of the sixty governments present[2].

The first part of the official record of the International Sanitary Regulations consists of the proceedings of the special committee, appointed by the Third World Health Assembly, and of the plenary session of the Fourth World Health Assembly. The second part of the volume contains the text of the Regulations with an explanatory memorandum, a table of comparison between the provisions of the Regulations and those of previous sanitary conventions and similar agreements, and an index to the Regulations. The Regulations are a revision and a consolidation of the text of the numerous previous conventions and agreements; they came into force for all member States of the World Health Organization (and also for those non-member States which so signify) on October 1, 1952.

Turning to the Regulations themselves, they are framed in the endeavour to secure maximum security against international spread of disease with minimum interference with world traffic. They revise and consolidate previous provisions on plague, cholera, yellow fever and typhus, including the Pan-American Sanitary Code, Havana, 1924. Relapsing fever, being suitable for control in ports, airports and at international frontiers, has been added. Supplementary regulations dealing with measures for preventing the spread of other epidemic diseases may be added from time to time, and already are envisaged as regards malaria.

It is required that the appearance of a quarantinable disease in a territory, and, if necessary, its continued existence, shall be notified to the Organization, which will report the information to all health administrations to which the Regulations apply. Thus health administrations will have a world-wide knowledge of the epidemiological situation of quarantinable diseases. In measures for the prevention of the importation of pestilential disease, it is intended that a State shall chiefly rely on its own public health service. The Regulations concerning plague, cholera, yellow fever, typhus and smallpox include all modern scientific methods of prevention. Vaccination is advised in the case of yellow fever; but not as regards typhus, because modern insecticides, properly applied, and disinfection where appropriate, afford adequate security. Rules governing the health control of the Mecca Pilgrimage have been added.

After reading the Regulations, including the procedure for acceptance, reservations and rejections, one obtains the impression that a great step forward has been made in the international control of epidemic disease. When all the governments of the world adopt the Regulations and implement them, they will protect not only their own frontiers from pestilence, but will also materially contribute to the health of all nations.

COPYRIGHT AND THE SCIENTIST

To the scientific man, nurtured in the tradition of the greatest possible freedom for the circulation and interplay of new scientific knowledge, anything that tends to restrict that freedom is liable to be irksome. If the Copyright Act of 1911 was guilty of causing (or more accurately of perpetuating) uncertainty among the general public as to the extent to which published works might be reproduced, it is not surprising that it should have appeared to the scientific worker to be something of a maze, any tortuous path of which might lead him to wrongdoing. Apart from such general uneasiness, three specific factors have in recent years given added point to the problem. First, and probably the least troublesome, the growth in the use made of review literature has brought out the need for some clearer definition of the degree to which a work might be quoted without infringement of the "fair dealing" provisions of the Act. Secondly, the copious increase in scientific and technical literature during the present century has brought with it a corresponding need for digests and summaries for convenient record by the research worker. Thirdly, advances in photo-copying and microphotography have simplified the reproduction of tables of results, technical reports and periodical articles and virtually removed the principal "disincentive" to copying, namely, the laborious process of manual transcription. If the Report of the Copyright Committee* set up by Mr. Harold Wilson, then President of the Board of Trade, in April 1951 does not entirely resolve these problems, it does provide a reasoned commentary on them and its recommendations will doubtless form the basis of any new legislation that may be introduced.

It says much for the good sense of scholars, authors and publishers alike that no test case has so far been brought in British courts. Yet it is virtually certain that the law of copyright, as it now stands in relation to the limited copying permissible of any work "for the purpose of private study, research, criticism, review or newspaper summary" has been frequently infringed in the scientific field. The facts that, first, infringement has probably taken place either in ignorance of the law or from a lack of understanding of the conception of published work as property; secondly, that no author or publisher has yet felt able to seek issue at law; and thirdly, that evidence of unlawful copying in cases of private study or research must be extremely difficult to obtain, only serve to emphasize that the present position is founded on fundamentally bad law. Two conflicting interests must be reconciled. On one hand, the scholar's interest demands that reasonable freedom to profit from the speed and cheapness of modern photographic methods of copying should be enjoyed, especially where original works are scarce or out of print. On the other, the author or his publisher—neither of whom may be responsible in these days for a work going out of print—quite reasonably foresees that indiscriminate and cheap photographic copying may substantially affect his own income.

---

* Report of the Copyright Committee, Cmd. 8662. (London: H.M.S.O. 4s. 6d. net.)

The Copyright Committee's diagnosis of this general problem is not at fault. What is debatable is whether the formula which it puts forward as machinery for the reconciliation of these two sets of interests rests upon a proper assessment of the nature of scientific communication. Broadly speaking, the Committee attempts to differentiate between the copying of periodical literature, books and manuscripts, a distinction of form rather than of content. The assumption is made—and for the purposes of science rightly made—that considerations of speed and currency lend the greatest importance to copying from periodical publications. Here it is proposed that, subject to certain statutory rules to be drawn up in consultation with organizations directly interested, any periodical literature should be available for copying. The minimum provisions of these rules which the Committee suggests is that copying should be done only by certain specified non-profit-making bodies, that the responsible librarian should satisfy himself that copies are genuinely required for private study or research, that one copy only of any one excerpt should be supplied to any one person and the excerpt restricted to one article, that the copy should not be supplied at less than cost price and that the applicant should give a written undertaking that the excerpt will not be used for other than its declared purpose. Apart from the question of designating the bodies under which such copying would be permitted, the proposals probably recognize, and are doubtless envisaged as giving force of law to, a procedure that is already not uncommonly adopted by learned societies and research libraries. Copying from books would be treated similarly except that the rules, since speed would not seem to be so essential, would enjoin some attempt to secure the author's or his publisher's permission before any "substantial" extract was copied.

It is not, however, sufficient to distinguish only between the various forms of printed publication. A more fundamental distinction lies between types of material published and, particularly, between works of creative imagination and papers or articles which bring scientific research data to public notice. While, on one hand, the author of a creative work expects to receive payment, and indiscriminate copying would be against his interests, for the scientific man, on the other hand, publication is rarely a matter of commercial reward. The scientific man's financial return is often nil, or a merely nominal sum. His real profit is in the form of an increase in professional reputation. Indeed, his interest, like that of scientific progress, demands that his work should be circulated as widely and as freely as possible. Some such notion doubtless lies behind the common practice among learned journals of making reprints of their papers readily available to contributors; and since this indicates acceptance by a considerable body of publishers of the advantages of the system, it is difficult to see that an extension of freedom to copy from scientific papers could do material harm. It should, of course, be required that every copy so made should bear a full reference to the original publication, and re-sale should be prohibited by law.

Needless to say, a general arrangement such as this would still be open to objections. Is it certain, for example, that works of creative imagination will not occasionally come near to being properly regarded as of scientific value? Is it reasonable to give the force of law to a permissive arrangement embodied in the Royal Society's "Fair Copying Declaration", and extend its application to all commercial scientific publishers in addition to those who have already accepted its provisions, together with many learned societies and other publishing agencies? How, if at all, would any general relaxation of copyright law in relation to scientific works affect British interests abroad under existing or contemplated international copyright conventions? Awkward as they are, it should not prove impossible to reach a fair solution of these problems. At the moment, it appears as though the Committee, in trying to please research worker, author and publisher alike and in treating all publication as a commercial investment, may have fallen into the trap of proposing statutory authority for a piece of cumbersome protective machinery which was created in self-defence against an anomalous and outmoded law. LESLIE WILSON

CHEMICAL RESEARCH LABORATORY, TEDDINGTON

REPORT FOR 1951

A PUBLICATION bearing the general title "Chemistry Research 1951"* includes the report of the Chemistry Research Board, signed by the chairman, Prof. E. L. Hirst, and the report of the Chemical Research Laboratory, Teddington, over the signature of the director, Dr. D. D. Pratt, together with the customary lists of publications during the year, standard substances and staff, and an alphabetical list of species in the National Collection of Industrial Bacteria, which now includes more than five hundred strains. Following a special review by the Board of the research programme and distribution of effort in the Laboratory, increased effort has been assigned to the purification of organic compounds and the precise measurement of physical properties, and to the microbiological production of sulphur. Work on the precise measurement of the vapour pressures and boiling points of bases of the pyridine series has been resumed, and greater effort has been given to the chemical side of the joint programme with the Physics Division of the National Physical Laboratory on accurate bomb calorimetry. A team from the Chemical Research Laboratory is now using for the microbiological reduction of sulphate the continuous process developed by the Ministry of Supply's Experimental Station at Porton.

* Department of Scientific and Industrial Research. Report of the Chemistry Research Board with the Report of the Director of the Chemical Research Laboratory for the Year 1951. Pp. iv+120+4 plates. (London: H.M. Stationery Office, 1952.) 4s. 6d. net.

Although the new Radiochemical Building of the Laboratory was expected to be ready for occupation, this would not suffice to meet the lack of accommodation stressed in the report for 1950; but that position should be alleviated by the new prefabricated building, specially designed for microbiological work, which was to be completed by the middle of 1952. (Both buildings have now been completed, see *Nature*, October 18, p. 648.) The Board's report stresses the extent to which fundamental work on corrosion is contributing to the solution of practical problems. Four model Scotch marine boilers have been installed on behalf of the British Shipbuilding Research Association for the Corrosion Group to investigate the corrosion produced in boiler tubes by the infiltration of salt water, and the Group is also advising the British Electricity Authority on the corrosion of boiler tubes in its generating stations. Use of potassium chromate containing chromium-51 in the study of corrosion inhibitors has indicated that the role of the inhibitor is not solely that of an oxidant keeping the iron oxide film in repair, and the radioactive tracer technique has already furnished information on the amount of chromium in the protective film and the distribution of the chromium over the surface. The use of electrode potential decay-curves has thrown further light on the mechanism by which sodium benzoate and potassium chromate inhibit corrosion, while good progress is reported in the fundamental work on the oxidation of massive metal surfaces. Other work has shown that sodium salts of the three nitrocinnamic acids and of *o*-nitrohydrocinnamic acid, at 0·5–1·0 per cent, inhibit the corrosion of cast iron as well as of zinc in distilled and mains water; the electrochemical investigation of the behaviour of painted steel panels in the solutions of various osmotic pressures continued, and electrochemical studies of anaerobic microbiological corrosion were started, as well as preliminary work on the effect of the cooling fluid on the turning of mild steel and on the application of vapour phase inhibitors for arresting corrosion in closed installations.

In the production and analysis of pure germanium for the Radio Research Board, the Inorganic Group has succeeded in reducing to about 1 part in 10^8 the arsenic content of germanium dioxide, produced from the tetrachloride, by distilling germanium tetrachloride in the presence of hydrochloric acid and chlorine. Further work on phosphatic fertilizers has been directed largely to the production of dicalcium phosphate and the recovery of the nitric acid used in attacking the phosphate rock. Besides a literature survey of the recovery of sulphur from calcium sulphate, the Group has continued to study the spectrophotometric determination of arsenic by the 'molybdenum blue' method; its spectrographic laboratories have been equipped with a 'multiservice unit' and a Beckman spectrophotometer with flame-photometer attachment, while efforts have been made to increase the speed of microchemical analyses of samples and to place on a sound basis the inorganic techniques required to deal with the increasing number of inorganic materials presented for analysis.

In the Radiochemical Group the scope of chromatographic methods has been extended to a wider range of metals, including tantalum and niobium, which are difficult to separate in other ways. Further improvements have been made in physical methods of analysis, and a polarographic method has been developed for continuously recording the variation in concentration of metal ions in solution, and a method devised for the measurement of carbon-14 operating in solution, based on a scintillation technique. Studies were carried out on the adsorption of gold, copper and iron from cyanide solutions by 'Amberlite I.R.A. 400' resin and of nickel, cobalt and zinc by 'ZeoKarb 225' cation-exchange resin, as well as on the precipitation of uranium and other metals from solution.

Much of the work of the Organic Group has been concerned with the provision of services to other organizations, and its preparative work has included, for example, the supply to the Medical Research Council for field trials in Africa of a sample of N_1N_3-*bis*-(4-aminocinnalyl-6-)guanidine, which has shown promising trypanocidal activity, a new synthesis of 2 : 6-hydroxybenzoic acid, the preparation and investigation of 2 : 3 : 5 : 6-tetrahydroxyterephthalic acid and its diethyl ester and attempts to prepare phloroglucinoltricarboxylic acid for investigation of its anti-rheumatic properties. Nearly five hundred samples of pure low-boiling hydrocarbons have been supplied to industrial and other laboratories in Britain for use as standards in calibrating mass spectrometers; α-picoline has been hydrogenated at 120–140° C. in the presence of *W*-6 Raney nickel catalyst, and benzene containing carbon-14 atoms has been synthesized, as well as ethylene oxide containing carbon-14 for use in insecticide studies.

The unique properties of polyvinyl alcohol membranes are being studied by the High Polymer Section for studies in osmometry and the exchange behaviour of large quaternary ammonium cations. A second series of sulphonated polystyrenes of different degrees of cross-linking has been prepared from a divinylbenzene solution supplied by the Dow Chemical Co., and the relative affinity coefficients are in general consistent with theories of ion-exchange equilibria which emphasize the importance of the size of the hydrated cation in the resin. Work has been commenced on the preparation of strongly basic resins by the chloromethylation of styrene, and, in work on the application of ion-exchange resins, β- and γ-resorcylic acids have been separated on an anion-exchange resin.

Fundamental studies in the Microbiological Section indicate that reducing agents enhance the viability of sulphate-reducing bacteria, and this finding has led to the development of a method for the accurate counting of live organisms. Work on the breakdown of organic compounds by these organisms has demonstrated the importance of pyruvic acid in their metabolism, and certain strains have been found which require no reducible sulphur when grown with pyruvates. Investigations on the inhibition of hydrogen absorption have continued, and those sulphate analogues found to be active inhibitors in manometric studies have been tested as inhibitors of the growth of the Hildenborough strain in sulphate-deficient *GPYS* medium; culture filtrates of this strain grown in *GPYS* and *LYS* media showed no trace of antibiotic activity against a wide variety of organisms. Further experiments have shown that elemental sulphur can be produced by the combined action of pure cultures of sulphate-reducing bacteria and the photosynthetic green or purple sulphide-oxidizing bacteria in a common medium and provide strong evidence that some of the sulphur in the Cyrenaican lakes was produced from sulphate by a similar combined action.

ROYAL GREENWICH OBSERVATORY

ANNUAL REPORT FOR 1951–52

THE annual report of the Astronomer Royal for the period May 1, 1951–April 30, 1952[*], deals with the three separate sections of the Royal Greenwich Observatory at Herstmonceux (including H.M. Nautical Almanac Office), Greenwich and Abinger, and provides an account of the work carried out at each place as well as a short description of the condition of the buildings. In some cases the progress of repair and reconstruction leaves much to be desired.

Approval has been given to the recommendation of the Board of Visitors that the old buildings of the Royal Observatory at Greenwich should be used as an astronomical and navigational annexe to the National Maritime Museum, and the trustees of the latter have received official intimation of this recommendation. The Astronomer Royal proposes leaving the historic instruments belonging to the Observatory in the old buildings at Greenwich—a decision which will give wide public satisfaction. The progress of the work with the 36-in. Yapp reflector at Greenwich has been disappointing, owing to further deterioration in the sky since the end of the Second World War, largely due to street lighting with mercury-vapour lamps, recently installed; a further reduction in the output of the telescope has been caused by illness among the observers. The programme of examining *K*0 sub-giants for luminosity effects correlated with anomalous trigonometric parallaxes is now directed towards fainter stars, and this, with the other factors, is responsible for the fact that only forty-six spectra of thirty stars have been obtained with the main reflector.

Time service throughout the year has been based upon astronomical observations made with the small transit *B* at Greenwich and the Bamberg broken-transit instrument at Abinger. A total of 509 observations at both places was made in the twelve months covered by the report, and an analysis of the performance of the clocks suggests that considerable changes occur in phase and amplitude of the annual fluctuations in the rate of rotation of the earth. The values obtained for 1950–51 are smaller than those given by many previous concordant analyses, and hence it is not practicable to apply corrections month by month to the time determined astronomically so as to produce a uniform time system. A time system that is approximately uniform is defined by the best quartz clocks, while the astronomical determinations of time over two or three years are used for giving the error and the rate for each clock.

Preliminary work has been started on the preparation of the Admiralty magnetic charts for the epoch 1955; the unfortunate dearth of recent observational data over many parts of the earth, particularly in central Asia and in the oceans, renders it extremely difficult to construct reliable current charts of secular variation. The employment of spherical harmonic analysis to improve the charts in regions where no observations have been made cannot be regarded as very satisfactory; the process is one of distributing the inaccuracies and is a poor substitute for the deplorable lack of observational data.

An important collaboration between H.M. Nautical Almanac Office and the Nautical Almanac Office, United States Naval Observatory, has resulted in the British "Air Almanac" and the "American Air Almanac" becoming a single publication bearing the title "The Air Almanac". Although printed separately in Great Britain and the United States, the two editions are printed photographically from identical material. This production represents a very important step in international co-operation, and the United States authorities have agreed to supply, at nominal cost, specially pulled proofs on glossy paper suitable for photographic reproduction to the official almanac-producing agency in any country. The International Civil Aviation Organization has recently directed the attention of contracting States to the availability of this Almanac for reproduction in other countries, with or without language changes, and it is hoped that it may eventually become international.

Some disappointment is expressed in the report at the slow progress in the removal of the Observatory from Greenwich to Herstmonceux. Nearly four years have passed since the first sections of the staff were moved to Herstmonceux; but the only instruments that have been installed are the spectroheliograph and spectrohelioscope, and the 26-in. and 28-in. refractors still remain dismantled at Herstmonceux. The Cook reversible transit circle is still at Greenwich, but no large programme of observations will be started with it until it has been installed at Herstmonceux. Increased industrial staff and, in consequence, increased expenditure attend the separation of the Observatory into three separate sections at Herstmonceux, Greenwich and Abinger, and, in addition, there is loss of flexibility and much administrative inconvenience. The most serious disadvantages of the division are the loss of observations and the lack of training in observing by many junior members of the staff. The meridian group, which is already far behind schedule, is to be proceeded with, but the financial cuts imposed this year have prevented a start on the construction of the equatorial group. The general situation is summed up by the Astronomer Royal towards the end of the report in the following words: "The slow progress in the removal from Greenwich to Herstmonceux is the cause of great disappointment and of a deep sense of frustration".

---

STANDING LIGHT WAVES

THE Rumford Medals awarded biennially by the American Academy of Arts and Sciences to the outstanding American contributors to the science of heat and light were established in 1796 by a gift of Benjamin Thompson, Count Rumford. It is customary for the recipient to present a communication to the Academy at the time of the receipt of the Medal, and in recent years he has usually reviewed significant aspects of his own work. The Academy, believing that the communications constitute a noteworthy record of American achievement in heat and light, has decided to publish a new series of the biennial Rumford Lectures, and the first of this series[*], entitled "Adventures with Standing Light Waves", is by Prof. H. E. Ives, who was awarded the Rumford Medal for 1951.

---

[*] *Proc. Amer. Acad. Arts Sci.*, 81, No. 1 (1951); "Adventures with Standing Light Waves" (Rumford Medal Lecture, 1951) (pp. 32; from the Academy, Boston, Mass., 1951).

The phenomenon of standing waves of light in the form of the Lippmann process was the subject of Prof. Ives's doctoral thesis some forty years ago. He then turned, during the First World War, to work on aerial photography, and after the War at the Bell Telephone Laboratories he was occupied at first with electrical contacts and then with the photoelectric effect, of which he made a close study. The various problems in the nature of the photoelectric effect, particularly the effect of the state of polarization of the exciting light on the photoelectric emission and the spectral distribution of the photoelectric emission from the alkalis, occupied his attention and led him to give an explanation in terms of the existence of a system of standing waves above the metal surfaces. This required for its test a knowledge of the optical constants of the alkali metals. Details of the experimental results obtained and their significance are discussed briefly by Prof. Ives. He stresses that it is the optical properties of the materials and the optical conditions of the region in which the phenomena occur which explain the outstanding effects, and that the various quantum mechanical explanations have almost uniformly neglected or ignored the optical factors.

Another experiment with standing waves of light referred to by Prof. Ives is a modification of Wiener's experiment, with a photoelectric film replacing the photographic film used by Wiener. Prof. Ives asserts that the verification of the electromagnetic wave theory of light furnished by this experiment considerably transcends that of Wiener's original simple experiment.

Finally, Prof. Ives discusses what contribution the results of these photoelectric experiments can make to the elucidation of the old question of the nature of light, waves versus corpuscles. Wiener's modified experiment, he claims, comes very close to showing both types of phenomena in combination. Wave mechanics is a way out of the dilemma. It avoids the unacceptable idea of photons by putting the quantum h in the atom and not in the radiation, and Prof. Ives concludes by predicting that the photon will go the way of the 'caloric' that Rumford demolished.

X-RAY AND NEUTRON MUTAGENIC EFFECTS ON CEREAL SEEDS

THE biological action of X-rays and fast neutrons on cereal seeds is the subject of detailed investigation in the Mutation Laboratory of the Swedish Seed Association at Svalöf, Sweden, use being made of the cyclotron equipment and other facilities of the Nobel Institute for Physics and of the Institute of Radiophysics at Stockholm (J. Mackey, *Arkiv. for Botanik*, **1**, 16, 545; L. Ehrenberg, A. Gustafsson and N. Nybom, *ibid.*, 557, 1952).

Both dry dormant and soaked seeds of wheat and barley were irradiated with X-rays and fast neutrons and the treated materials followed through two generations for observation of the frequency of primary chromosome disturbances, the retarding effect on sprouting, the death-rate, the induced degree of sterility in the first generation, and the frequency of certain types of mutation in the second. For the production of genetically interesting and useful materials, neutrons are many times more effective than X-rays; at high neutron dosages the mutation-rate reaches a very high level. Cells with low water content (and low metabolic activity) are highly resistant to the killing effects of neutrons as compared with X-rays, but actively dividing cells are more sensitive to neutrons; after neutron irradiation, about five times as many cells show chromosome disturbances in pre-soaked as compared with dry seed.

Different radiations may act in different ways because of differences in ionization density, distribution of ionizing rays within the object, and the duration of the time of action of isotopes. The general result so far obtained is that neutrons are about ten times as effective as X-rays of equivalent energy dissipation in causing chromosome disturbances and from fifty to one hundred times as effective in causing first-generation sterility and in increasing the rate of mutation. This higher effectiveness is attributed to the difference in ion density. While the results reported are not regarded as final, they constitute an important advance in the planned and controlled induction of mutations in agricultural and horticultural plants by ionizing agents.

CYTOCHROME COMPONENTS IN CHLOROPLASTS

By H. E. DAVENPORT

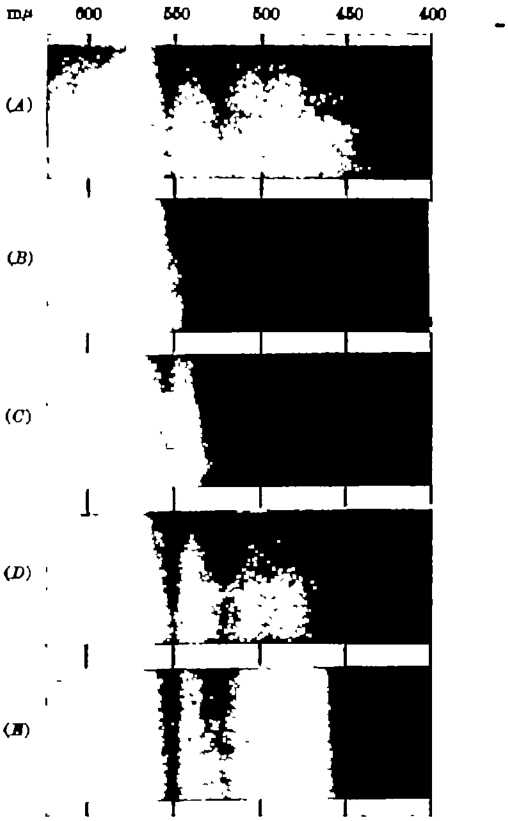
School of Biochemistry, University of Cambridge

LITTLE was known of the distribution of components of the cytochrome system in green leaves until Hill and Scarisbrick[1] separated not only cytochrome *c* but also two new soluble components, b_6 and *f*. Cytochrome *f* appeared to be confined to chlorophyll-containing tissues where the presence of high concentrations of plastid pigments precludes the direct spectroscopic observation of the component. It was first observed in the reduced form in preparations of leaves from which plastid pigments had been removed by acetone treatment. Afterwards, Hill and Scarisbrick obtained cytochrome *f* in solution in ethanol extracts of fresh leaves. In solution it is not autoxidizable, does not combine with carbon monoxide and has, in the reduced form, a characteristic spectrum with the α-band at 555 mμ. Further properties of the purified cytochrome have been described in greater detail[2] and evidence presented for supposing that it may play an important part in the electron transfers occurring in photosynthesis. Hitherto, however, cytochrome *f* has been observed only in preparations which had been treated with organic solvents, and the possibility therefore remained that it was an artefact arising from some other hæmatin compound as a result of that treatment. It has now been found that the absorption spectrum of cytochrome *f* can be observed directly in intact plastids prepared from etiolated barley leaves.

Barley seedlings were grown on John Innes seedling compost in a darkened incubator at about 20° C. After nine days, the yellow leaves were harvested and 10-gm. amounts were ground in a chilled mortar with 10 ml. of cold 0·5 *M* glucose in 0·03 *M* phosphate buffer of *p*H 7·4. The material was squeezed through muslin and centrifuged for 1 min. at 3,000 r.p.m. to remove intact cells and vascular debris. The turbid yellow supernatant fluid was centrifuged at 4,000 r.p.m. at 2° C. for a further 5 min. This gave a yellowish brown sediment which when viewed with the Zeiss microspectroscope against a strong light showed the spectra of carotenoids, protochlorophyll and a little chlorophyll *a* and also a sharp band at 555 mμ, the position of the α-band of ferrocytochrome *f*. The cloudy supernatant fluid was recentrifuged at 12,000 r.p.m. for 10 min. to give a second precipitate showing a similar spectrum.

The two precipitates were suspended separately in about two volumes of the cold glucose solution and examined microscopically. The second precipitate appeared to be mainly fragments of plastids, whereas the first precipitate consisted of intact plastids similar in form to the chloroplasts extracted from normal green barley leaves by the same procedure. The latter have been found to have high activities in the photochemical chloroplast reaction described by Davenport, Hill and Whatley[3]. Similarly[4] it has been shown that etiolated barley plastids will reduce an indophenol dye in light, and that this activity increases progressively with the development of chlorophyll when the leaves are greened by exposure to light. For further examination and the photography of spectra, the suspended precipitates were combined in a cell 0·5 cm. thick. The photographs of absorption spectra were made in collaboration with Dr. R. Hill, using a diffraction-grating camera arrangement designed by him[5].

Immediately after resuspension of the precipitates, the band at 555 mμ is relatively faint; but at room temperature it slowly increases to a maximum density in about 30 min. (Fig. *B*). Shaking then again results in an immediate decrease in density, suggesting that systems are present which can catalyse the oxidation of cytochrome *f* by oxygen. On the addition to the suspension of a trace of ferricyanide, the band at 555 mμ disappears as the cytochrome is completely oxidized. If, on the other hand, a trace of a reducing agent (sodium hyposulphite) is added there is no change in the band of ferrocytochrome *f*, but two additional bands then appear (Fig. *C*) : a faint band at 605 mμ corresponding to cytochrome *a* of yeast and a strong band at 563 mμ in the position of the *b* group of cytochromes. Cytochrome *c* could not be detected visually in the preparations. To facilitate comparison of the spectrum of the reduced plastids with more typical cytochrome systems, the spectra of reduced yeast cells and muscle granules[6] are shown in Figs. *D* and *E*. By comparing visually the intensities of the α-bands of the components in the reduced plastid suspension with those in a variable thickness of compressed baker's yeast, it was possible to obtain an approximate measure of the relative concentrations of the components in the two types of material. Here it was necessary to compare the band of cytochrome *f* in the plastids with that of cytochrome *c* in the yeast. On the basis of the absorption spectra of the two cytochromes in solution this comparison is valid[6]. These measurements gave the following concentration ratios : *a* (yeast)/*a* (plastids) = 10 ; *b* (yeast)/*b* (plastids) = 1·6 ; *c* (yeast)/*f* (plastids) = 4. The concentration (v/v) of plastids in the suspension used was similar to that estimated for the living cell. Moreover, Hill and Scarisbrick[1] have shown that leaf hæmatin is concentrated largely in the plastids and is not distributed evenly through the cell. These ratios may therefore be held to represent a direct comparison of the concentrations of the components in the living cells of leaves and yeast.



Absorption spectra of cytochrome components. (*A*) Dilute solution of cytochrome *f*. (*B*) Suspension of etiolated barley plastids in air. (*C*) Suspension of etiolated barley plastids + sodium hyposulphite. (*D*) Compressed baker's yeast, 1 mm. thickness. (*E*) Granule preparation from pigeon breast muscle

The spectrum of the reduced plastid preparation does not change in an atmosphere of carbon monoxide. By adding an equal volume of pyridine to the reduced suspension, bands of the corresponding pyridine hæmochromogens appear with centres at 585 mμ (*a*), 558 mμ (protohæmochromogen = *b*) and 551 mμ (*f*). The presence of large concentrations of carotenoid pigments in the preparations entirely prevented observation of the β- and γ-bands of the cytochrome components.

It was confirmed that cytochrome *f* can be extracted by ethanol from both etiolated and normal barley leaves. Leaves (10 gm.) were ground in a chilled mortar with 9 ml. of 96 per cent ethanol containing 0·06 ml. of ammonia solution (spec. grav. 0·88). The material was squeezed through muslin and centrifuged. When viewed with the microspectroscope in a layer 2 cm. thick, the characteristic band at 555 mμ was visible in the clear supernatant fluid.

The above preliminary observations appear to confirm that cytochrome *f* is a normal constituent of the chloroplast. Its abundance in the intact plastids and the relative absence of cytochrome *c* is in marked contrast to the considerable uniformity shown by the cytochrome systems of animal tissues and yeast and also by the colourless, non-photosynthesizing portions of higher plants[7,8]. There is still no direct evidence of the role of the component in the metabolism of the chloroplast; but it is hoped that further work with partially etiolated material may throw light on this problem.

I have to express my gratitude to Dr. R. Hill for his interest in this work. I am indebted to Mr. J. B. Chappell for a preparation of muscle granules. Thanks are also due to the Agricultural Research Council for providing the special facilities for this work.

OCCURRENCE OF GAMMA-AMINO-BUTYRIC ACID IN EXTRACTS OF *PISUM SATIVUM* (L.) AND IN THE HONEYDEW OF *MYZUS CIRCUMFLEXUS* (BUCK.)

By J. L. AUCLAIR and J. B. MALTAIS

Division of Entomology, Science Service Laboratory, Canada; Department of Agriculture, St. Jean, Quebec

THE occurrence of gamma-amino-butyric acid in biological material has been reported occasionally. Dent[1] mentioned its possible occurrence in human blood and urine. Steward *et al.*[2] definitely identified it as a constituent of the potato tuber; next to the amides glutamine and asparagine, it was the most abundant soluble nitrogen constituent in the potato, amounting to 540 µgm. per gm. of fresh tuber. Awapara *et al.*[3] and Roberts *et al.*[4] reported the occurrence of free gamma-amino-butyric acid in the human brain. Reed[5] also found this compound in yeast.

In investigations on the factors of plant resistance to insects, analyses of free amino-acids in pea-plant extracts were carried out by paper partition chromatography. Two-dimensional chromatograms yielded a large number of amino-acid spots, one of which appeared at the position usually occupied by methionine sulphoxide (Fig. 1, No. 14). Before a further test, a few plant extract samples were oxidized at mild heat with hydrogen peroxide and a catalyst in order to convert methionine sulphoxide quantitatively into methionine sulphone. The test revealed only a trace of the sulphone on the two-dimensional chromatograms. The large methionine sulphoxide spot remained mostly unchanged. This observation led to some uncertainty as to the identity of the methionine sulphoxide spot. The R_F values of this particular spot were 0·73 in phenol – water and 0·21 in collidine – lutidine – water by the method of capillary ascent. Other samples were run with the following solvent system: phenol – water in the first dimension and *n*-butanol, 300 ml.; glacial acetic acid, 60 ml.; and water, 140 ml., in the second dimension. This procedure resulted in the separation of the 'methionine sulphoxide' spot into two components: a faint spot that remained at the methionine sulphoxide position with an R_F of 0·31 in butanol – acetic acid – water (Fig. 2, No. 14), and a large dense spot that appeared just below the valine spot with an R_F of 0·50 (Fig. 2, No. 20). The position of this new spot did not correspond with that of any of the well-known amino-acids.

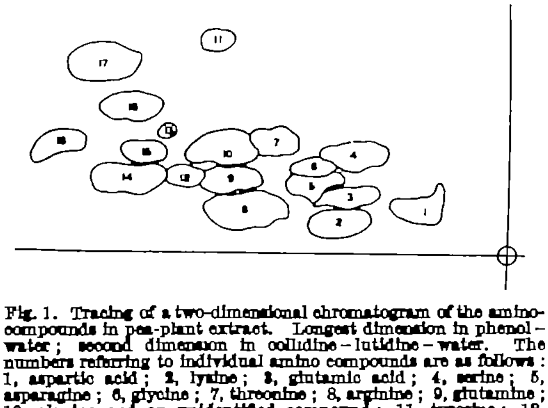

Fig. 1. Tracing of a two-dimensional chromatogram of the amino-compounds in pea-plant extract. Longest dimension in phenol – water; second dimension in collidine – lutidine – water. The numbers referring to individual amino compounds are as follows: 1, aspartic acid; 2, lysine; 3, glutamic acid; 4, serine; 5, asparagine; 6, glycine; 7, threonine; 8, arginine; 9, glutamine; 10, alanine and an unidentified compound; 11, tyrosine; 12, β-alanine; 13, α-amino-butyric acid; 14, methionine sulphoxide and γ-amino-butyric acid; 15, possibly β-amino-isobutyric acid; 16, valine; 17, leucine and/or isoleucine and phenylalanine; 18, proline

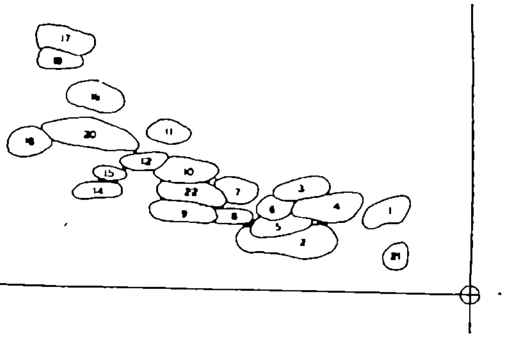

Fig. 2. Tracing of a two-dimensional chromatogram of the amino-compounds in pea-plant extract. Longest dimension in phenol – water; second dimension in butanol – acetic acid – water. The numbers referring to individual amino compounds are as follows: 1, aspartic acid; 2, lysine; 3, glutamic acid; 4, serine; 5, asparagine; 6, glycine; 7, threonine; 8, arginine, 9, glutamine; 10, alanine; 11, tyrosine; 12, β-alanine; 14, methionine sulphoxide; 15, possibly β-amino-isobutyric acid; 16, valine; 17, leucine and/or isoleucine; 18, proline; 19, phenylalanine; 20, γ-amino-butyric acid; 21, cystine; 22, an unidentified amino compound concealed by alanine in Fig. 1

The basic copper carbonate ($CuCO_3$, $Cu(OH)_2$) test described by Crumpler and Dent[6] as a distinctive test for alpha-amino-acids in paper chromatography was applied with positive results. When samples of pea-plant extracts were separated on two-dimensional chromatograms previously treated with the basic copper carbonate powder, a single spot appeared after the ninhydrin reaction. This single spot, on chromatograms irrigated with phenol – water in the first dimension and collidine – lutidine – water in the second dimension, was situated at the methionine sulphoxide position. The results obtained with the basic copper carbonate test indicated that the unidentified compound is not an alpha-amino-acid.

Of the new amino-compounds other than alpha-amino-acids recently reported as occurring in biological material, gamma-amino-butyric acid and beta-amino-isobutyric acid were those having the R_F values closest to the methionine sulphoxide position. Pure samples of the two compounds were secured, and the above experiments were repeated; gamma-amino-butyric acid matched exactly the R_F of the methionine sulphoxide spot in phenol – water and collidine – lutidine – water chromatograms. Moreover, upon the addition of a small amount of gamma-amino-butyric acid to pea-plant extracts before chromatographic analysis, there was a significant increase of the 'methionine sulphoxide' in the first solvent system and of the 'below valine' spot in the second solvent system. These results, together with the evidence given by the basic copper carbonate test, leave no doubt as to the presence of gamma-amino-butyric acid in the pea plant. This amino-acid is an addition to the list of those identified in peas by Auclair and Maltais[7].

Gamma-amino-butyric acid was also identified in the honeydew excreted by *M. circumflexus* feeding on potato plants. It is very likely that the aphids take this compound from the host plant, which contains a relatively large amount of it. A complete chromatographic analysis of amino-acids in the honeydew of this insect feeding on potato has been effected by Maltais and Auclair[8].

A quantitative estimation of gamma-amino-butyric acid in pea-plant extracts was made by the method of quantitative paper chromatography developed by Auclair and Dubreuil[9]. On a dry-weight basis, the quantity of gamma-amino-butyric acid is approximately 11 mgm. per gm. of pea-plant sample. On a fresh-weight basis, the amount is approximately 1,680 μgm. per gm. The amount found in the potato tuber, as given by Steward *et al.*[2], is 540 μgm. per gm. In the honeydew of *M. circumflexus* feeding on potato, the quantity of gamma-amino-butyric acid is estimated at 0·6 mgm. per gm. of dry matter. The significance of the occurrence of this compound in relation to plant resistance to insects is being studied.

It is probable that another spot appearing above methionine sulphoxide, not as yet identified on chromatograms of pea-plant extracts, may be beta-amino-isobutyric acid. The R_F of this compound corresponds to the spot above methionine sulphoxide (Fig. 2, No. 15). Further tests are being carried out on its identification.

We are grateful to Dr. F. C. Steward and Dr. J. F. Thompson, Department of Botany, Cornell University, for their generous supply of pure gamma-amino-butyric acid. Thanks are also extended to Dr. Lester J. Reed, Department of Chemistry, University of Texas, for a gift of pure synthetic beta-amino-isobutyric acid. [Feb. 14.

PEPSINOGEN IN HUMAN SEMINAL FLUID

By Dr. FRANK LUNDQUIST and Dr. HANS HENRIK SEEDORFF

University Institute of Legal Medicine, Copenhagen

EARLIER investigations have shown the presence in human semen of proteolytic enzymes responsible for the degradation of the fibrin-like material which causes the clotting of semen (Lundquist[1]). The presence of at least two different proteolytic enzymes, an amino peptidase hydrolysing leucinamide, glycylglycine, triglycine and glycyl-leucine, and a 'protease' has been established[2].

We have now been able to show that apart from these enzymes, with a pH optimum around 7·5, there is also present in seminal fluid an enzyme which has optimal activity at very acid reaction, namely, about 2·5. As it was considered unusual for a cathepsin to show activity at such high hydrogen-ion concentration, the possibility was investigated that the enzyme in question was pepsin, or some closely related proteolytic enzyme.

Figs. 1 and 2 show a comparison of the pH-activity curves for the seminal enzyme preparation and ordinary swine pepsin, using as substrates serum proteins (as described by Bucher[3]), and edestin (prepared from hemp seed according to Bailey[4]). The hydrolysis was followed colorimetrically with phenol reagent and copper sulphate[5]. The very close relationship with pepsin was confirmed by the fact that coagulation of milk was produced by enzyme preparations that had been acidified and neutralized again.

The enzyme preparations employed in these experiments were purified in the following way: pooled samples (50–70 ml.) of seminal plasma (we are indebted to "Sygekasselægernes organisations centrallaboratorium" for considerable quantities of human semen) are precipitated between 40 and 70 per cent saturation with ammonium sulphate at pH 6. The precipitate is dialysed thoroughly against distilled water for at least 24 hr. The residue, after centrifugation, contains practically all the pepsinase activity present in the original semen and no activity at neutral pH, whereas the supernatant contains the other proteolytic enzymes. Extracts of the precipitate with 0·9 per cent sodium chloride are used for further experiments. Extracts prepared in this way contain the enzyme as a proenzyme, which is converted to pepsin when the pH is lowered to 3–4. This was shown by the following experiments:

(*A*) ***Milk coagulation test.*** When the solution is mixed with skim milk at pH 5·4 (0·1 ml. enzyme + 1 ml. milk) no coagulation takes place. If the enzyme solution is acidified to pH 2 and carefully readjusted to pH 5·4 after a few minutes, coagulation takes place 2 min. after mixing with milk.

(*B*) ***Instability in alkaline solution.*** When the extract prepared as described above is kept at room temperature for 18 hr. at a pH of 8·5, no appreciable reduction in activity takes place. If, however, before

Fig. 2. Activity of seminal enzyme (circles) and swine pepsin (crosses) as a function of pH. Substrate, 2 per cent edestin in citrate; 2 ml. substrate + 0·5 ml. enzyme. Temperature, 37° C. Time, 60 min. Activity expressed as per cent of the maximal value

incubation the *p*H has been brought to 2·5 and back to 8·5, practically all activity has disappeared. This instability at faintly alkaline and even neutral reaction is a characteristic property of pepsin.

The accompanying table shows the results of experimental comparison of the activity towards various substrates of seminal pepsinase, crystalline swine pepsin and human pepsin made from gastric juice. The enzymes were diluted to approximately the same strength towards serum protein. For the serum protein, 2 ml. of a 10 per cent dialysed solution of dry serum at *p*H 2·5 was incubated with 1 ml. enzyme for 1 hr., followed by precipitation of proteins with trichloroacetic acid and phenol reagent and addition of copper sulphate and sodium carbonate to an aliquot of the filtrate. Edestin was used in the same way, but the concentration of protein was only 2 per cent; colour was developed in the same way as for serum proteins. For the milk test, 0·1 ml. of enzyme was added to 1 ml. of skim milk at *p*H 5·4, and the time was measured for the first sign of flocculation. In the test with carbobenzoxy-glutamyl-tyrosine, the substrate concentration was 0·0015 *M* and the *p*H 2·5; the samples were incubated at 37° C. for 18 hr. and deproteinized with tungstic acid; the hydrolysis in this case was measured by the ninhydrin method as described recently by Baker[6]. The close similarity in the rates of hydrolysis is best seen when the ratio between human gastric pepsin and seminal pepsin for the four substrates are compared (last column).

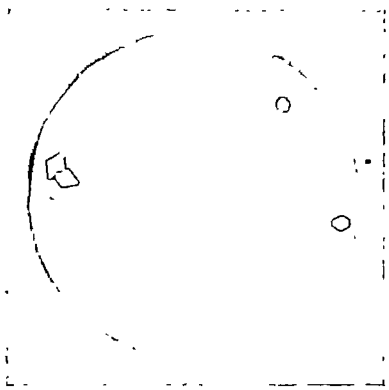

Fig. 3. Pepsin crystals obtained from human seminal plasma

The activity of pepsinogen in normal semen corresponds to 0·002 mgm. pepsin per ml., which is of the same order of magnitude as that found in gastric juice.

As pepsin was one of the first enzymes to be prepared in the crystalline state, we tried to crystallize the enzyme from human semen. The methods described by Northrop[7] were not applicable in our case, because they require very concentrated solutions; but the following procedure led to the crystallization of seminal pepsin. The saline extract (already described) was dialysed against distilled water for 36 hr. The precipitate was extracted with isotonic saline and centrifuged for 20 min. at 25,000 *g*. The supernatant was again dialysed, and the small amount of precipitate extracted with 0·05 *N* hydrochloric acid. The clear supernatant after centrifugation for 30 min. at 25,000 *g* was dialysed for 24–48 hr. at 5° C. against distilled water. By this procedure crystals were obtained. They have not been isolated free of amorphous material, and the quantities of crystalline enzyme are exceedingly small, so that we have not so far been able to make analyses and to tackle the question of the identity of pepsin from semen and gastric juice. The crystals are, however, indistinguishable both as regards appearance and size from those prepared from pure swine pepsin using the same procedure, and correspond well with the description given by Northrop (compare Fig. 3).

Concerning the site of formation of pepsinogen, our preliminary experiments indicate that it is formed in the vesicular glands. The function of pepsinogen in semen presents a very puzzling problem, the main difficulty being how activation takes place. It must be considered very improbable that the *p*H of semen at any time after ejaculation into the female genital tract can be exposed to *p*H values low enough to bring about activation. If, on the other hand, activation has taken place, one might imagine some process analogous to milk coagulation, which takes place at more physiological *p*H values.

One possibility has appealed to us, namely, that pepsinogen is adsorbed to the surface of the sperm cells, and that the acid metabolic products excreted by the cells might bring about a local high acidity, enabling the proenzyme to be converted into pepsin. Experiments with epididymal bull spermatozoa have shown, however, that less than one thousandth of the cell surface is covered with pepsinogen when a dense suspension of living cells is mixed with pepsinogen solution. Work on this problem will be continued on other animal species.

Determination of Neutron Resonance Parameters from Measurements of the Absorption Integral : Application to the Main Resonance of Uranium-238

THE resonance absorption of neutrons has been extensively studied by the time-of-flight technique[1]. If the resolution is insufficient to resolve the true shape of the resonance curve, it is sometimes possible to determine the absorption cross-section σ_0 at exact resonance and the width Γ of the Breit–Wigner resonance formula from a study of the variations with absorber thickness of the absorption integral :

$$A(n) = \int (1 - T)\mathrm{d}E = \int (1 - \exp - n\sigma(E))\mathrm{d}E, \quad (1)$$

where $\sigma(E)$ is the cross-section of the absorbing nuclei and n the number of nuclei/cm.^{2}. Experimentally, the absorption integral is found as the area of the dip in the measured curve of transmission against neutron energy. This area is independent of the resolution.

If the resonance is sharp, that is, the width is small compared to the resonance energy, the asymptotic behaviour of $A(n)$ for large n has been shown to be

$$A_{as} = (\pi n\sigma_0\Gamma^2)^{1/2}. \quad (2)$$

In treating the results of absorption integral measurements, it is convenient to express them in the form :

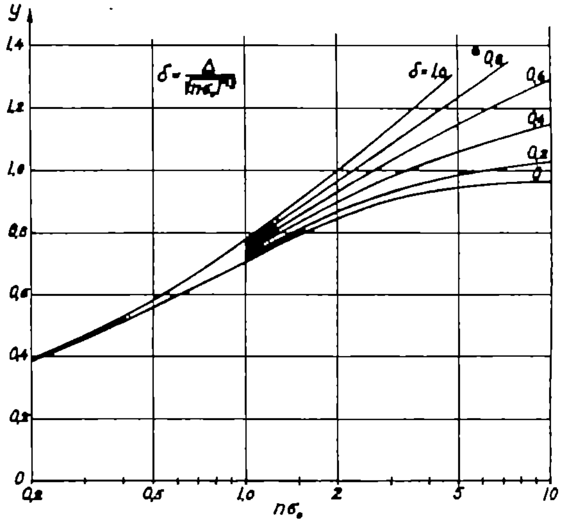
$$y = (A/A_\infty)\,(n_\infty/n)^{1/2}, \quad (3)$$

where A_∞ results from the measurement on an infinitely thick absorber. If the Breit–Wigner formula is assumed to hold and the resonance is sharp, we have for atoms at rest :

$$\begin{aligned} y_0 &= (4\pi n\sigma_0)^{-1/2}\int_{-\infty}^{+\infty} [1 - \{\exp - n\sigma_0/(1 + x^2)\}]\,\mathrm{d}x \\ &= (\pi n\sigma_0)^{-1/2}\int_0^z\int_{-\infty}^{+\infty} \{\exp - 2t/(1+x^2)\}\,(1+x^2)^{-1}\,\mathrm{d}x\mathrm{d}t \\ &= (\pi/2z)^{1/2}\int_0^z (\exp - t)\,I_0(t)\mathrm{d}t \\ &= (\pi z/2)^{1/2}\,(\exp - z)\,[I_0(z) + I_1(z)], \end{aligned} \quad (4)$$

where $z = n\sigma_0/2$.

The intermediate step leading to the introduction of a Bessel function $I_0(z)$ of imaginary argument makes use of the integral expression quoted by Bethe[2]. The final result is obtained by partial integration[3]. The function y_0 has previously been calculated by numerical integrations by Havens and Taylor[4]. If the width Γ of the resonance cannot be regarded as large compared with the Doppler width Δ, the Breit–Wigner cross-section curve has to be averaged over the velocity distribution of the scattering atoms.



We have :

$$y = (4\pi n\sigma_0)^{-1/2}\int_{-\infty}^{+\infty} [1 - \{\exp - n\sigma_0\psi(\Gamma/\Delta,x)\}]\mathrm{d}x, \quad (5)$$

where[2]

$$\psi(\Gamma/\Delta,x) = \pi^{-1/2}\,(\Gamma/2\Delta)\int_{-\infty}^{+\infty} [\exp - \{(\Gamma/2\Delta)(x-y)\}^2]\,(1+y^2)^{-1}\,\mathrm{d}y. \quad (6)$$

The integrations (5) and (6) can no longer be carried out analytically, but it is possible by series expansion of the integrands of (5) and (6), and subsequent integration term by term, to obtain y in the form of a power series of δ^2, where

$$\delta = \Delta/(n\sigma_0\Gamma^2)^{1/2}. \quad (7)$$

This power expansion will converge only as long as $\Delta/\Gamma < 1$. For larger values of Δ/Γ the integrations (5) and (6) have been performed numerically. In the accompanying graph, y is plotted as a function of $n\sigma_0$ with δ as a parameter.

For very thick samples ($n\sigma_0 \gg 1$) the expansion

$$y_{as} = 1 - \frac{1}{4}(2z)^{-1} - \frac{3}{32}(2z)^{-2}\ldots + \frac{3}{2}\delta^2\left(1 - \frac{5}{4}(2z)^{-1}\ldots\right) - 45/8\,\delta^4\ldots \quad (8)$$

is obtained.

To determine the resonance parameters from measurements of the resonance integral for a thin and a thick sample, the thick sample is first assumed to be infinitely thick and δ and y for the thin sample calculated. The graph then gives a first approximation to σ_0. From this the function y for the thick sample is calculated using (8) and is applied as a correction factor to δ and y for the thin sample, yielding a second approximation for σ_0.

For optimum accuracy the thickness of the thin sample should be chosen roughly in the region of

Sample (gm./cm.^{2})	n (cm.$^{-2}\times10^{24}$)	A (eV.)	y	δ	$n\sigma_0$	σ_0 (cm.$^2\times10^{-24}$)
5·46	0 0115	0 670 ± 0 050	1 00	0·14	(53)	
3·45	0 00727	0 560 ± 0 040	1 05	0·17	(34)	
0 67	0 00144	0·265 ± 0·030	1·12	0·39	> 3 3	> 2,000
0·27	0·00051	0·170 ± 0·025	1 14	0 62	2·3 – 10 5	4,000–18,000
0·092	0·000194	0 065 ± 0·010	0 75	1·06	0·60–1·30	3,100–6,700

maximum slope of the graph, if it is assumed that the absorption integral measurements have the same absolute accuracy. For atoms at rest this corresponds to a value of $n\sigma_0$ of about 1·0, while the Doppler effect tends to increase the optimum thickness. If the thin sample is made very thin, the result becomes independent of the Doppler effect, but the accuracy is low.

The procedure has been applied to measurements on the main resonance of uranium described elsewhere[5]. The samples were uranium oxide of thicknesses listed in column 1 of the table. Uranium oxide has a Debye temperature of about 140° K.[6], and the effective temperature[7] of the sample is thus almost equal to the room temperature, the Doppler width Δ being 0·052 eV., assuming a resonance energy of 6·6 eV.[4,8]. The value of σ_0 has been given in the last column as an upper and lower limit resulting from estimated mean square errors of the absorption integral measurements. While the accuracy of the measurements is rather low, it is seen that the results are quite consistent.

Angular Distribution of the Neutrons from the Reaction $^7Li(d,n)^8Be$

Using 680-kV. deuterons from the Van de Graaff generator at the University of Bergen, we have measured the energy spectrum and the angular distribution of the neutrons from the reaction ^{7}Li(d,n)^{8}Be. The energy spectrum of the neutrons has been found by measuring the recoil protons in photographic emulsions for the following angles ω, between the d and n directions in the laboratory system: 0°, 20°, 50°, 90°, 110°, 120° and 140°. A total of about 10,000 proton tracks, forming a maximum angle of 10° with the incident neutrons, have been investigated.

The energy spectrum for ω = 140° is given in Fig. 1. Neutron groups are found corresponding to energy-levels in beryllium-8 at 2·9, 4·1 and 5·0 MeV. These results are in good accordance with previous measurements by Green and Gibson[1].

The energy spectra for the smallest three ω-values also indicate the existence of an energy-level at 2·2 MeV. The relative intensities of the neutron groups change with the angle ω.

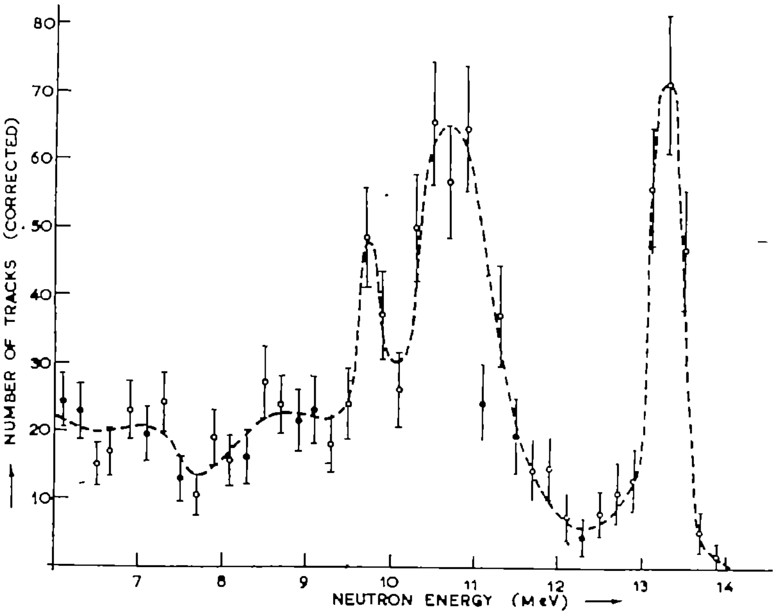

Fig. 1. 140° neutron spectrum

The angular distribution in the centre-of-mass system of the neutrons corresponding to the ground-state and the 2·9-MeV. excited state of beryllium-8 is given in Tables 1 and 2 and Figs. 2 and 3 respectively, the values in both cases being normalized to 1·00 for ω = 0°.

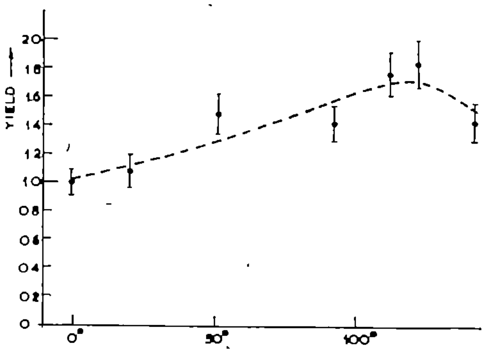

Fig. 2. Angular distribution in the centre-of-mass system of the reaction ^{7}Li(d,n)^{8}Be

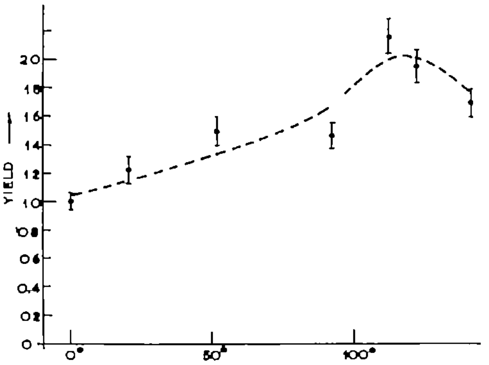

Fig. 3. Angular distribution in the centre-of-mass system of the reaction ^{7}Li(d,n)^{8}Be*

141·3°	1·70 ± 0·10

No theory for the angular distribution of the neutrons from (*d*,*n*)-reactions has so far been worked out for low deuteron energies. The Butler theory[2] of a stripping process, originally worked out for deuteron energies between 7 and 15 MeV., has since been extrapolated to lower energies[3].

On the basis of this theory and the angular distribution curves in Figs. 2 and 3, we may conclude that both the stripping process and the compound nucleus formation are operative at the *d*-energy used in our experiment[4].

Growth Spirals originating from Screw Dislocations on Electrolytically Produced Titanium Crystals

ACCORDING to the theory of Burton, Cabrera and Frank[1], crystals can only grow at supersaturations too low for two-dimensional nucleation, when dislocations are present. Where a screw dislocation terminates in a crystal face, an exposed edge is formed which, while growing, will persist and develop as a 'growth spiral' centred on the dislocation. This theory has been applied to the electrolytic production of titanium crystals.

In the course of work on the production of titanium by electrolysis of fused salt, we have obtained a number of large titanium flakes which are single crystals as revealed by X-ray examination. These hexagonal flakes have, in the main, flat (0001) basal plane surfaces. On further examination using a metallographic microscope and employing the techniques described by Griffin[2], growth spirals originating from screw dislocations have been observed on these surfaces. This is the third reported instance where direct visual evidence of screw dislocations has been obtained on metal crystals and is the first case of screw dislocations being responsible for crystal growth in electrolysis.

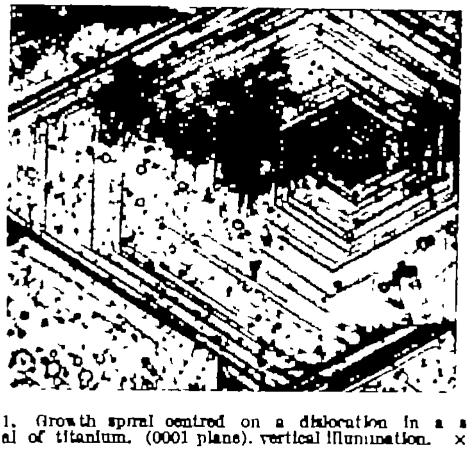

Fig. 1. Growth spiral centred on a dislocation in a single crystal of titanium. (0001 plane). vertical illumination. × 200

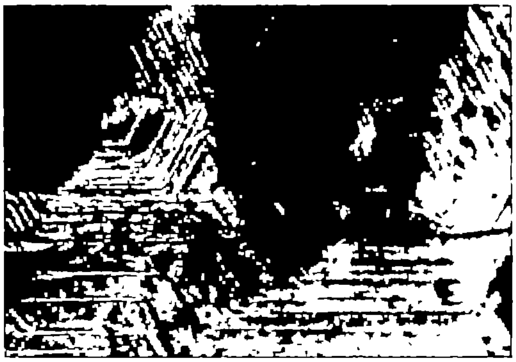

Fig. 2. Growth spirals of the opposite hand joining to form closed loops. 'In focus' technique (ref. 1). × 200. (Note mechanical twin through growth layers)

The first visual proof for the presence of dislocations in metals was obtained by Amelinckx *et al.*[3], when growth spirals originating from screw dislocations were observed on the (111) faces of gold crystals obtained by precipitation. Triangular and hexagonal growth spirals were observed and step-heights of the order of 400 ± 100 A. were measured.

More recently, Forty[4] has observed spiral growths originating from screw dislocations on the (0001) surfaces of magnesium crystals obtained in the form of thin hexagonal flakes by sublimation. The growth layers were estimated to be either one or two atoms in thickness. (The step-heights were less than 20 A.)

Growth spirals centring on multiple dislocations have been observed on our titanium single crystals (Fig. 1). The average step-height, measured by multiple-beam interference fringes of the Fizeau type, obtained with parallel, monochromatic light at normal incidence, was 240 ± 100 A. Some difficulty was experienced in making the measurements due to surface irregularities, and a technique similar to the one recently described by Tolansky and Omar[5] was used.

It is evident that most of these spirals cannot be due to dislocations of unit strength (1/2 $d_{(0001)}$ = 2·37 A.) but are generated by groups of dislocations all having the same sign and having a resultant Burgers vector with a component normal to (0001) of approximately 100 A. However, in some cases, no deviation of the fringe system could be seen, showing that the steps are less than 100 A.

Besides multiple spirals originating at the same dislocation centres, spirals of opposite sign, interacting so as to form closed loops, have been observed, in accordance with theory (Fig. 2).

In all cases, after the first few turns of these growth spirals, they became hexagonal in form, following the hexagonal outline of the crystal and denoting the strong influence of the crystal orientation on the radial growth velocity of the titanium crystals.

One other observation that should be mentioned is the following. Some crystals have been obtained which are series of built-up hexagons of which the edges (10$\bar{1}$0) show growth lamellæ of the type observed on zinc and cadmium deposited from vapour by Straumanis[6]. These layers are about 3000 A. in thickness on our electrolytically produced titanium and are not to be confused with the growth spirals observed in the centres of the (0001) faces of these crystals. When these layers are complete over the length of the crystal edge, the hexagonal type of growth spirals is obtained as shown in Figs. 1 and 2.

A complete description of the observations and techniques used will be reported elsewhere.

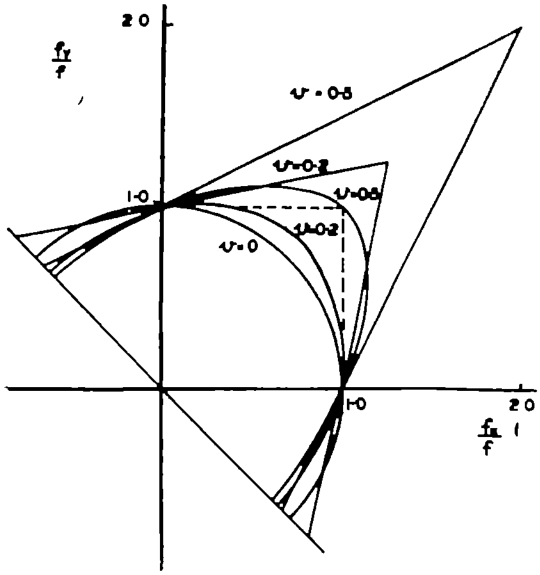
Mechanism of Fracture of Concrete

H. J. COWAN's[1] hypotheses for the fracture of concrete are very similar to those already proposed by Prof. M. Roš[2]. Such hypotheses usually rely mainly on the observations of failing loads of specimens for their justification, and proceed from the assumption that concrete may be regarded as a homogeneous isotropic material. In the Division of Building Research of the Commonwealth Scientific and Industrial Research Organization, an extensive experimental study has been made of the strain distribution in various types of concrete specimen, using one concrete mix throughout. The results suggest that in all specimens the first failures occur when the tensile strain is about 10^{-4}. In compression tests of cylinders, this strain occurs when the load is about fifty per cent of the ultimate, and in unreinforced flexural specimens at about ninety per cent of the ultimate. The measurements made here also show how widely the concrete strains may vary in a region in which they are theoretically uniform.

These results concerning maximum tensile strain and the development of tensile cracks in specimens before the maximum load is reached are confirmed by other workers[3-5]. Our tests suggest that a noticeable decrease in the gradient of the compressive stress–strain curve coincides with the formation of tensile cracks on the circumference of a cylindrical compression specimen. I believe that the so-called shear failure is a secondary development which occurs after the vertical splitting has begun. It may be of interest to note that Wästlund[6] claims to have shown that the plane of so-called shear failure in compression specimens is actually a plane perpendicular to the maximum tensile stresses.

In the accompanying graph the ratio of the stress at fracture to the uniaxial tensile strength is plotted for various hypotheses of failure for a range of stresses from $f_x = -f_y$ to $f_y = -f_x$. The hypotheses chosen are maximum normal stress (straight broken lines), maximum normal strain (straight full lines) and maximum total strain energy per unit volume (curved full lines). It is desired to show the extent to which the limit provided by each hypothesis may vary according to the value assumed for Poisson's ratio. In this graph the extremes for $\nu = 0$ and $\nu = 0 \cdot 5$ are shown (the maximum strain theory with $\nu = 0$ coincides with the maximum stress theory). These are undoubtedly extremes, but such values have been proposed for concrete under certain conditions[4,7].



Since Poisson's ratio itself may vary widely for one mix, and in the range of values most commonly accepted ($0 \cdot 1 < \nu < 0 \cdot 25$) the limiting curves for all hypotheses lie close together, the difficulty of choosing any one hypothesis, principally on an observation of the loads and hence the stresses, during the test becomes obvious. A complete set of strain measurements for the effective part of the test specimen is also essential.

Enhancement of Auroral Hydrogen Lines towards Lower Latitudes

MANY years ago, I suggested that the bundles of solar electric rays which produce the auroræ and most magnetic disturbances are composed of electrons electrostatically neutralized by positive ions of great specific charge, mainly protons[1-4].

On this view the current density (i) of a bundle composed of electrons and protons is given by

$$i = ne\,(V_e - V_p), \qquad (1)$$

where n is the number of electrons or protons in unit volume, and V_e and V_p are the velocities of the electrons and protons respectively.

The number of electrons ν_e and protons ν_p entering unit cross-section perpendicular to the direction of the current in unit time is $\nu_e = nV_e$, and $\nu_p = nV_p$. Thus the velocity of the protons (V_p) relative to that of the electrons (V_e) essentially determines the relative intensity of the hydrogen lines in the auroral luminescence.

A bundle constituted in this way, being magnetically active, produces the magnetic fields responsible for the magnetic perturbations, and at the same time it is deviated in the earth's magnetic field.

In a magnetic field of intensity F, each unit volume is acted on by a force K given by the equation :

$$K = F.en\,(V_e - V_p)\sin\varphi, \qquad (2)$$

where φ is the angle between F and the direction of the current density in the point, and K is perpendicular to the vectors F and i.

The correctness of this view regarding the constitution of the solar ray bundles was proved when, in the years 1939–41, it was found that hydrogen lines occasionally appeared with considerable intensity in the auroral luminescence, and that they showed a pronounced Doppler displacement corresponding to velocities of the order of 10^8 cm./sec. [5-8].

Thus the proton velocities may vary from very small values corresponding to extremely small intensities of the hydrogen lines to values at least up to 2,000–3,000 km./sec., while the electrons have velocities of the order of 10^{10} cm./sec., and are thus mainly responsible for the magnetic activity of the bundle.

On account of their much greater mass, the protons may have a dominating influence on the magnetic deviability of the bundle. It is easily shown that for proton velocities greater than about 10^7 cm./sec., the radius of curvature of the protons will be greater than that of the electrons, provided electrons and protons could move independently of each other.

Thus the increase of proton velocities, which means greater intensity of the hydrogen lines, will increase the magnetic stiffness of the bundle, with the result that the auroræ are driven away from the magnetic axis point and towards lower latitudes. Consequently, we should expect that the relative intensity of the auroral hydrogen lines, for a certain magnetic meridian, would increase with magnetic polar distance or towards lower latitudes.

Since the auroral hydrogen lines and their Doppler displacement were detected about twelve years ago, a considerable number of strongly exposed auroral spectrograms have been obtained both at Tromsoe and Oslo. The intensities of the H_β-lines were found relative to the negative nitrogen band 4709 and expressed by the ratio $I_{(H\beta)}/I_{(4709)}$ [10].

At Oslo we obtained twelve, and at Tromsoe eleven, spectrograms showing a quite strong band at 4709.

The mean values of the ratio $I_{(H\beta)}/I_{(4709)}$ derived from these spectrograms were: Oslo, 1·01; and Tromsoe, 0·15.

Thus the observational results, so far as they go, show a considerable increase of the relative intensity of the auroral hydrogen lines towards lower latitudes, in agreement with the consequences drawn from the proposed constitution of the solar ray bundles.

A Microwave Vibration Wattmeter

IT has been shown[1] that mechanical forces exerted by an electromagnetic field can be employed to make absolute measurements of microwave power at levels of a few watts or more. Experiments carried out in this department by Mr. I. M. Stephenson have shown that the same method can be used to measure a few tens of milliwatts of power at a wave-length of 3·2 cm. by making use of a vibration-free table and amplifying the resulting small deflexion by means of a photo-cell and galvanometer.

However, the apparatus is rather inconvenient in use, and it is the purpose of this communication to describe a new principle which greatly increases the sensitivity. Mechanical resonance is used to increase the deflexion obtainable, but at the same time electrical resonance is employed in an unusual way. The power to be measured passes along a wave-guide terminated by a high-Q cavity. A short horizontal dipole is suspended by its mid-point by a quartz fibre inside the cavity, and tends to align itself parallel with the unperturbed electric field. When the dipole makes an angle of 45° with this direction, the cavity is resonant at the frequency at which power is to be measured, and is matched to the input wave-guide. It is arranged that a very small change in this angle detunes the cavity completely.

Consider the dipole at rest in the 45° position. Suppose microwave power is admitted to the cavity by means of a wave-guide switch. The dipole will experience a torque, tending to turn it clockwise, say. A very small clockwise rotation will suffice to reduce the torque to a negligible amount, but the dipole has then acquired some angular momentum, and it will continue its clockwise swing to an angular position $45° + \theta_1$ determined by the restoring force of the fibre and frictional forces. When this limit is reached, the oscillator is switched off, and the dipole swings anticlockwise to an angle which, if the frictional forces are small, is almost equal to $45° - \theta_1$. If the oscillator is switched on again, the dipole again experiences a torque as it passes through 45°. This time it swings to a new limiting position $45° + \theta_2$, θ_2 being greater than θ_1, and the cycle of events is repeated until a constant amplitude of mechanical oscillation is reached, from $45° + \theta_0$ to approximately $45° - \theta_0$. It can be shown that the angle θ_0 is given by:

$$\theta_0^2 \doteqdot \frac{P}{2f} \cdot \frac{M}{c} .$$

In this formula P is the power delivered to the cavity at resonance, f is the frequency, c is the specific couple of the quartz fibre, and M is the 'mechanical magnification' defined as the ratio of the initial amplitude to the decrease in amplitude per period for natural oscillations.

The remarkable feature of this result is that it is independent of the Q-factor of the cavity and of the characteristics of the dipole. This is because the increase in torque at resonance which arises from an increase in Q-factor or length of dipole is exactly compensated by the reduction in the time during which the cavity stays in tune, so that the *impulse* received is unchanged. Because of this independence, the method is particularly attractive at millimetre wave-lengths, when accurate measurements of Q-factor, etc., are not very readily accomplished.

Another feature of importance is that θ_0 is proportional to $\sqrt{(P/f)}$, whereas in the instrument described previously[1] the deflexion is proportional to P/f. It follows that the new method has the advantage that the deflexion falls off less rapidly with decreasing power and increasing frequency. However, the formula quoted above is only valid when the angular rotation of the dipole required to detune the cavity to $1/\sqrt{2}$ of the amplitude at resonance is small in comparison with θ_0. If this condition is not met, a correction including the Q-factor must be introduced.

Preliminary experiments at a wave-length of 3·2 cm. show that an adequate deflexion (~ 30 cm. at 1 metre) can be obtained easily with a power of 100 mW. or less.

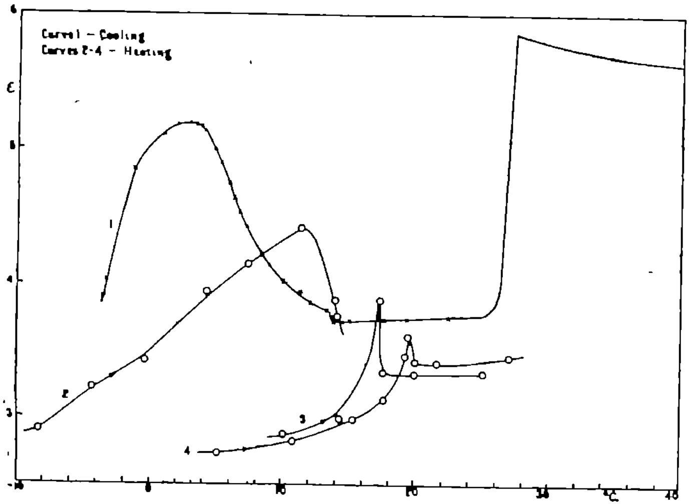
Dielectric Observations of Nucleation

Certain long-chain ketones of equal chain-lengths but different position of the keto group have such similar properties as to be reminiscent of isotopes and are yet nearly mutually immiscible in the solid state. Mixtures of equal amounts of a sufficient number of such 'equivalent' ketones are, however, stable either as a single-phase solid solution or as a multiphase mixture of the constituents[1]. Mixtures of this kind are exceptionally suitable for a study of precipitation, since all constituents are precipitated simultaneously. Recent measurements of dielectric properties carried out during the precipitation of such a mixture yield information on early stages of nucleation and on the dielectric properties of small aggregates.



Dielectric constant of a mixture of five ketones in the course of precipitation

The mixture investigated consisted of equal amounts of five equivalent ketones of the formula $C_mH_{2m+1}.CO.C_{17-m}H_{35-2m}$, with m equal to 3, 4, 5, 6 and 7. The multiphase form of the mixture is stable up to the melting point at 27·5° C., but the metastable single-phase form, which shows a polymorphic transition at 13·5–15·5° C., can be preserved indefinitely above the temperature of this transition. On cooling below this temperature, complicated phenomena occur in the mixture which find expression in its dielectric properties.

The accompanying graph shows the dielectric constant of the mixture at 800 c./s., during different heat-treatments. Curve 1 was obtained during cooling of the specimen, while curves 2, 3 and 4 were obtained on heating after the specimen had been annealed for varying times at temperatures below 4° C. The longer the time of annealing, the smaller is the peak observed and the higher the temperature at which it occurs. Specimens annealed for some weeks retain their low dielectric constant up to the melting point, and their structure, as indicated by X-ray powder photographs, is that of the multiphase form.

The experimental evidence may be interpreted as follows. On cooling below the temperature of the polymorphic transition the mixture becomes capable of precipitation, and aggregates are formed which have comparatively high dielectric constants while they are small and/or imperfect. These aggregates are thermodynamically unstable, and on annealing at low temperatures they change gradually into more stable aggregates of lower permittivity. On reheating, the aggregates are dissolved, at a temperature which is the higher the more stable they have grown, and during their dissolution they pass again through the condition connected with high dielectric constants.

The evidence indicates a sequence of intermediate stages of precipitation, depending in a complicated way on time and temperature. In this respect the mixed ketones are analogous to age-hardening alloys[2], and their study might be of interest to metallurgists. Compared with alloys, the ketones offer two advantages for the investigation of precipitation: precipitating aggregates form the bulk of the material and are not dispersed in a matrix, and their properties can be studied by very sensitive dielectric methods.

The comparatively high permittivity of the precipitating aggregates is of interest from the point of view of dielectrics: even though the permittivity of the solid mixture remains below that of the liquid, the evidence indicates a possibility of obtaining high dielectric constants with some kinds of small or imperfect aggregates. The relaxation times of dipoles in such aggregates are also of interest. From the points of view of the theories either of phase changes in solids or of dielectrics, it would obviously be interesting to correlate the physical properties of the precipitating aggregates with their structure. Work on this is in progress.

We wish to thank Mr. C. G. Garton for many helpful discussions and the Director of the Electrical Research Association for permission to publish this communication.

A Superstructure in Spinels

IN 1935, E. Kordes[1] recognized that $LiAl_5O_8$ has nearly a spinel structure, but he observed a large number of extra lines, which he could not explain. A. Hoffman[2] prepared the corresponding compound $LiFe_5O_8$, which again was recognized as having nearly spinel structure. We found[3] that the powder diagrams of $LiFe_5O_8$ correspond with a primitive cubic lattice with a lattice constant of 8·33 A. The space group was found to be very probably $P4_33$ (or $P4_13$) and the positions of the atoms (in the notation of the International Tables, 1935) are:

$P4_33$ 4 Li at 4 (b)
12 Fe „ 12 (d) with $x = $ [illegible] $+ \Delta_1$
8 Fe „ 8 (c) „ $x = 0 + \Delta_2$
24 O „ 24 (e) „ $x = $ [illegible] $+ \Delta_3$, $y = $ [illegible] $- \Delta_4$, $z = $ [illegible] $+ \Delta_5$
8 O „ 8 (c) „ $x = $ [illegible] $+ \Delta_6$

with Δ_3, Δ_4, Δ_5 and Δ_6 approximately 0·007 and Δ_1 and Δ_2 still smaller.

For all Δ's equal to 0, this would mean an ideal spinel lattice with an ordered arrangement of lithium and iron ions in the ratio 1 : 3 over the octahedral sites. The type of the order is best described by considering only the sixteen octahedral interstices. These are occupied by four lithium and twelve iron ions in such a way that each lithium ion is surrounded by six iron ions in an octahedron elongated along a trigonal axis and each iron ion by four iron and two lithium ions.

Single crystals of $LiFe_5O_8$ have been grown and investigated and the above deductions are fully confirmed.

Below 735° C. the four lithium ions are distributed in this ordered way over the sixteen octahedral interstices. The long-range order decreases only very slowly up to this temperature. Above 755° C. the long-range order has completely disappeared and the four lithium ions are distributed over the sixteen octahedral interstices only. Up to at least 1,000° C. they do not enter to an appreciable extent into the tetrahedral interstices.

Between 735° and 755° there exists a transition region where the equilibrium long-range order vanishes within a temperature-range of a few degrees. The transition velocity above 755° C. and below 735° C. (down to 450° C.) is very high (transition within a few seconds to a minute). Between 735° and 755° there exists a region where the transition to the equilibrium is extremely slow. By rapid quenching from 950° C. we obtained the disordered phase at room temperature.

$LiAl_5O_8$ shows the same type of superstructure, but the order–disorder transition takes place at much higher temperature. We obtained the disordered phase by quenching from 1,350° C.

Some specimens of γFe_2O_3, prepared by E. W. Gorter of this laboratory, gave very nearly the same diagrams as $LiFe_5O_8$. They proved to contain some water molecules. In these γFe_2O_3 specimens the type of ordered structure described for $LiFe_5O_8$ is present, which in the ideal case would require a ratio of 1 : 3 for the ordering elements. In the description of γFe_2O_3 as a spinel with vacancies[4], $Fe_8(Fe_{13\,^1/_3}\Delta_{2\,^2/_3})O_{32}$, the ratio of vacancies to iron ions at the octahedral interstices would be at most 1 : 5. The ratio ideal for ordering would be reached by incorporating water molecules, approaching the formula HFe_5O_8 as a limiting formula.

Recently, Houben[5] has shown by absorption measurements that the compound HAl_5O_8 also exists under certain conditions. As shown by Ervin[6], the transition from boehmite to αAl_2O_3 and goethite to αFe_2O_3 through the γ oxides can be regarded as a gradual rearrangement of the aluminium and iron ions in the cubic close-packed oxygen framework. Since the products of the first transition steps are only nearly anhydrous, the very mobile protons might be expected to play an important part in these transformations. In special cases such as the γFe_2O_3 preparations mentioned, they can even give rise to a highly ordered superstructure in the γFe_2O_3 phase, thus showing that they are not merely present as absorbed water.

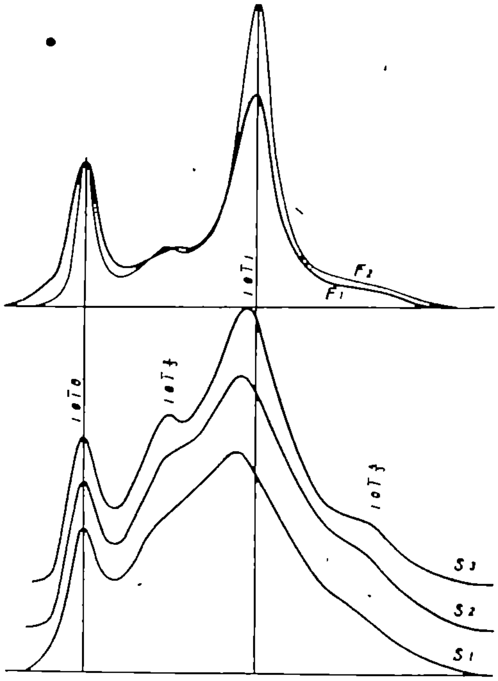
Crystal Distortion of Graphite in Cast Irons

RECENTLY, Debye–Scherrer line-breadths, the parameters of unit cells and the proportions of α- and β-modification of graphite present in cast irons, have been published by W. S. Owen and B. G. Street[1]. In connexion with this and other work, I have investigated the variation of disordered structure within a graphite grain by removing, step by step, outer layers of the grains by an oxidizing agent, since the variation seems to exist if we consider the crystal growth of irons.

The graphite samples used were a coarse flake graphite in a commercial grey cast iron, and a temper graphite in a commercial black-heart malleable cast iron of pipe fittings. The graphites were extracted from the cast irons by dissolving with hot dilute hydrochloric acid and washing with hydrofluoric acid. Then the outer layer of the grains was dissolved by wet oxidization. Many examples are known[2] of penetration of foreign atoms between the layer planes of the graphite crystal by the action of liquid agents; this results in the increase of the lattice parameter normal to the layer planes. In the present treatment it is necessary that the oxidizing agent should attack gently and uniformly over the grain surface without destroying inner structure. For this purpose, the samples were boiled in an 8 per cent solution of potassium dichromate mixed with sulphuric acid (sp. gr., 1·29) in a flask fitted with a reflux condenser. The grain size of the powder gradually decreased as the boiling continued; after 12 hr. in the case of the flake graphite, most of the grains became hexagonal in shape or fragments of hexagons, although the initial shape was irregular and only in rare cases were hexagonal figures observed on the grain surface.

The Debye–Scherrer patterns of these specimens were obtained by using copper $K\alpha$ rays and a camera



of 20-cm. radius. The intensity distribution curves of a portion of interest in the diffraction patterns are shown in the accompanying diagram, in which the curves have been reduced to the intensity scale from the microphotometer curves by using step-sector marks, the $10\bar{1}0$ line being made of constant height. The peaks of this line are arranged so as to lie on a vertical line. Curve $F1$ (thick line) was obtained with the flake graphite before the dichromate treatment, and curve $F2$ (thin line) with the same specimen oxidized for 12 hr. (weight loss 75·6 per cent). As will be seen from the latter curve, the lines are markedly sharper and the $10\bar{1}1$ line is enhanced. Curves $S1$, $S2$ and $S3$ were obtained with the temper graphite specimens oxidized for 0 hr., 2 hr. (weight loss 32·2 per cent) and 12 hr. (weight loss 74·6 per cent) respectively. It will be seen that the breadth of the lines corresponding to the α- and β-modifications of graphite decrease successively, and the peaks of the $10\bar{1}1$ line shift towards the position for the perfect crystal as the grain-sizes decrease. In addition, the increase in intensity of the $10\bar{1}\frac{1}{3}$ and $10\bar{1}\frac{2}{3}$ lines of β-graphite is noticeable. However, further sharpening of the lines was not observed after the reduction of the grain size by further oxidization up to 24 hr. (weight loss 98·2 per cent).

From these results, it can be concluded that the crystal structure is more perfect in the region of the core of the grains where the crystals were first formed. In order to examine the effect of crystal distortion which might be produced when preparing the specimen rod, a slit specimen holder with a slit width of 0·1 mm. was employed in place of the specimen rod, the powdered specimens being placed in front of the slit. X-Rays diffracted by the powder reach the photographic film after passing through the narrow slit, and hence very sharp lines are produced. With this device, a sharp 0002-line of the flake graphite was obtained, while the line broadened due to the orientation of the crystals when an extruded specimen was used. It has been confirmed that the general features of the diffraction patterns are similar to those shown in the present diagram; however, the appearance of spots on some lines of the flake graphite, due to the coarse grain, made the film inadequate for microphotometry.

Work-hardening of Annealed Mild Steel under Static and Dynamic Conditions

IT was found by Meyer[1] that when a hard ball is pressed into the surface of a metal by a force F, thus forming an impression of diameter d, the relation

$$F = kd^n \qquad (1)$$

holds, where k is a constant depending upon the metal and ball diameter and n, the Meyer index, is a constant depending only upon the metal. The Meyer index is 2·0 for metals which do not work-harden, for example, materials already fully worked, whereas for materials which do work-harden n is greater than 2·0, the greatest value being about 2·5. It has so far only been possible to examine equation (1) under conditions of static loading, but recently a method has been described for the continuous measurement of force throughout impact[2], and this has been adapted for the measurement of the index n under dynamic conditions. The force used for this purpose is the maximum force of impact, and the diameter is the diameter of the impression left after impact.

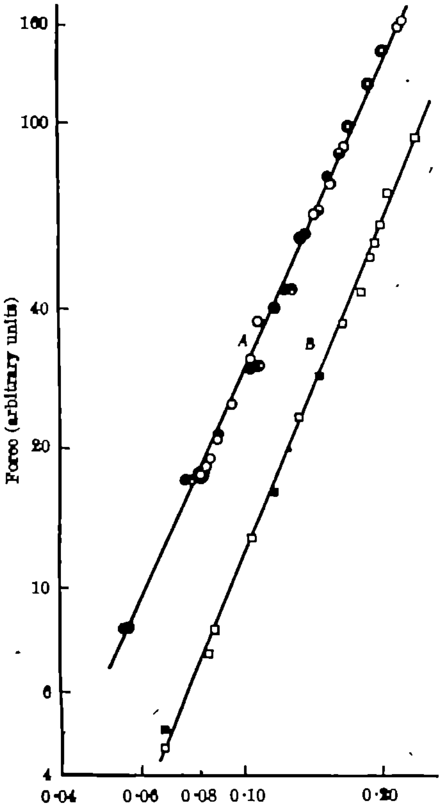
Static and dynamic measurements have been made with ⅛-in. (0·32-cm.) diameter ball-bearing indenters upon the same specimen of annealed mild steel. The diameters of both sets of impressions covered the same range, the smallest diameter being greater than 0·1 of the ball diameter, ensuring that all the measurements are in the fully plastic regime. In dynamic tests the maximum force was reached in about 300 μsec., and in static tests the maximum force was maintained for one minute.

The accompanying graph shows log–log plots of the forces as functions of the diameters of the impressions. In each case the points fall near straight lines, the slopes being the indices. The dynamic slope (2·20 ± 0·04) is less than the static slope (2·39 ± 0·05). The t test shows that the probability of this (0·19) or a greater apparent difference arising by chance is less than 0·1 per cent; the result is highly significant. The interpretation offered is that a lesser degree of work-hardening occurs under dynamic conditions than in static tests.

It is particularly important to check this interpretation, as workers with some materials have recently questioned the value of the Meyer index as a guide to work-hardening[3]. It might be expected from equation (1) that the ratio of the Vickers hardnesses (H_2/H_1) of the materials at the centres of static impressions of diameters d_2 and d_1 should be given approximately by

$$\log (H_2/H_1) = (n - 2) \log (d_2/d_1). \qquad (2)$$

This has been tested; an experimental value of the ratio was 1·43, and the calculated value 1·59. This confirms that in static tests with annealed mild steel,



The forces as functions of the diameters of impressions made in (*A*) impacts, (*B*) static tests. (The relative position of (*A*) to (*B*) is arbitrary in the vertical direction)

the work-hardening predicted by equation (1) does, in fact, occur. A further check has been made. The static and dynamic indices of the same specimens were measured after the specimens had been cold-worked by compressing them to half their original thickness. It is to be expected with fully worked material that both static and dynamic indices should be 2·0 ; the values found were 2·08 ± 0·04 for the static index and 2·09 ± 0·03 for the dynamic index. This observed equality of the indices also shows that the earlier observed difference was not simply due to instrumental effects.

It therefore appears that in impact the deformed material is not work-hardened to the same extent as in a static test. This difference might be permanent or temporary. If permanent, the difference between the indices leads to the expectation that, for impressions of diameter 0·22 cm., the Vickers hardness at the centres of those formed in impact should be about 20 per cent less than the corresponding hardness of static impressions. Forty impressions of 0·22 cm. diameter were formed statically in the annealed material and forty dynamically. The mean hardness at the centres of static impressions was 164 ± 2 kgm. mm.$^{-2}$, and at the centres of dynamic impressions, 166 ± 2 kgm. mm.$^{-2}$. (The mean hardness of the undeformed material from forty tests was 95 ± 1 kgm. mm.$^{-2}$.) Therefore, it is concluded that the lesser degree of work-hardening which occurs in impact is temporary, the mild steel changing after the impact to the same state as exists after a static test. Other materials are being examined and already similar effects have been found.

I gratefully acknowledge the help of Mr. B. Jones, who has made many of the measurements.

Angular Momentum in Dirac's New Electrodynamics

TYABJI[1] recently determined the canonical and symmetrical energy momentum tensors of Dirac's[2] new theory of electrodynamics. Tyabji used the conventional definition of the canonical energy momentum tensor and symmetrized this tensor in the traditional manner[3-5]. The canonical tensor

$$T_{\rho\sigma} = \frac{\partial(kv_\lambda)}{\partial x_\sigma} F_{\rho\lambda} + \frac{\partial\xi}{\partial x_\sigma} F_{\rho\mu} \frac{\partial\eta}{\partial x_\mu} + \frac{\partial\eta}{\partial x_\sigma} F_{\mu\rho} \frac{\partial\xi}{\partial x_\mu} + \delta_{\rho\sigma} L \tag{1}$$

given by Tyabji can be written without the explicit appearance of the ξ and η variables, as follows :

$$T_{\rho\sigma} = F_{\rho\mu} F_{\sigma\mu} + F_{\rho\mu} \frac{\partial k v_\sigma}{\partial x_\mu} + \delta_{\rho\sigma} L ; \tag{2}$$

or

$$T_{\rho\sigma} = F_{\rho\mu} F_{\sigma\mu} - \lambda v_\sigma v_\rho + \delta_{\rho\sigma} L + \frac{\partial}{\partial x_\mu} (k v_\sigma F_{\rho\mu}). \tag{3}$$

The symmetrizing tensor[1], $T'_{\rho\sigma} = \frac{\partial G_{\mu\rho\sigma}}{\partial x_\mu}$, is

$$T'_{\rho\sigma} = - \frac{\partial}{\partial x_\mu} (k v_\sigma F_{\rho\mu}) \tag{4}$$

or

$$T'_{\rho\sigma} = - \lambda v_\sigma v_\rho - F_{\rho\mu} \frac{\partial k v_\sigma}{\partial x_\mu}. \tag{5}$$

(5) simply removes the unsymmetrical mixed term of (2) and adds the 'matter' contribution to the energy momentum tensor to yield[1]

$$\theta_{\rho\sigma} = T_{\rho\sigma} + T'_{\rho\sigma} = F_{\rho\mu} F_{\sigma\mu} - \lambda v_\sigma v_\rho + \delta_{\rho\sigma} L. \tag{6}$$

If (3) is added to (4), the canonical tensor contains the 'matter' term, and the symmetrizing tensor cancels the mixed last term of (3). λ is a scalar function of x_μ, and can be interpreted as the rest mass density of the streams of electrical charge.

The conservation of energy and momentum is ensured by the vanishing divergence of (6). The divergence of (6) can be written

$$\frac{\partial \theta_{\rho\sigma}}{\partial x_\rho} = \frac{\lambda}{k} \left(v_\rho F_{\rho\sigma} - k v_\rho \frac{\partial v_\sigma}{\partial x_\rho} \right), \tag{7}$$

and vanishes by virtue of Lorentz's equation

$$v_\rho F_{\rho\sigma} = k v_\rho \frac{\partial v_\sigma}{\partial x_\rho} = k \frac{d v_\sigma}{ds}, \tag{8}$$

which is a consequence of the Dirac theory.

The angular momentum, based on $\theta_{\rho\sigma}$, is equal to the sum of the 'field' angular momentum and the 'matter' angular momentum. Angular momentum is conserved, because $\theta_{\rho\sigma}$ is symmetrical and divergence free. In the usual classical formulation of the Maxwell field, the angular momentum is automatically resolved into orbital and spin components[4]. This decomposition is not justifiable on physical grounds, and, in addition, it is not gauge invariant. If one associates a spin density with $G_{omn} - G_{onm}$, customary Maxwell theory yields the non-gauge-invariant $E_m A_n - E_n A_m$, whereas Dirac's theory yields $E_m k v_n - E_n k v_m$. In space-time regions where there is electric charge, the latter expression seems to be unique. For space-time regions where there is no charge, the Dirac spin density, in the Lagrangian formulation of his theory, seems to be indeterminate, because v_μ is indeterminate[2].

The Energy Momentum Tensor in Dirac's New Electromagnetic Theory

TYABJI[1] has shown that the energy momentum tensor in the vortical form of Dirac's new electromagnetic theory[2] has the same form as that belonging to the non-vortical theory. The method he uses of first obtaining a non-symmetrical form and then adding a suitable symmetrizing term depends on the particular definition of the electromagnetic potential A_μ and thus does not show why the two energy momentum tensors should have the same form.

The energy momentum tensor can be obtained by a different method, namely, by writing the metrical tensor $g_{\mu\nu}$ explicitly in the Lagrangian function L and then considering the variation of the integral $\int L \sqrt{-g}\, dx^1 dx^2 dx^3 dx^4$ with respect to $g_{\mu\nu}$.

In the non-vortical form of Dirac's theory, one has :

$$L = -\tfrac{1}{4} g^{\mu\sigma} g^{\nu\tau} F_{\sigma\tau} F_{\mu\nu} + \tfrac{1}{2}\lambda (g^{\mu\nu} A_\mu A_\nu - k^2), \qquad (1)$$

and in the vortical form :

$$L = -\tfrac{1}{4} g^{\mu\sigma} g^{\nu\tau} F_{\sigma\tau} F_{\mu\nu} + \tfrac{1}{2}\lambda' (g^{\mu\nu} v_\mu v_\nu - 1), \qquad (2)$$

where

$$v_\mu = k^{-1} \left(A_\mu - \xi \frac{\partial \eta}{\partial x^\mu} \right) \qquad (3)$$

and

$$\lambda' = k^2 \lambda. \qquad (4)$$

While a velocity vector is usually regarded as contravariant, the v_μ defined in Dirac's vortical theory is initially covariant, so that v_μ is independent of $g_{\mu\nu}$ and $v^\mu = g^{\mu\nu} v_\nu$. For this reason the covariant v_μ is used in (2). Variation with respect to $g_{\mu\nu}$ gives directly the symmetrical form of the energy momentum tensor obtained by Tyabji. Since the velocity vector in the non-vortical theory is defined by $v_\mu = k^{-1} A_\mu$, and since (1) and (2) contain $g_{\mu\nu}$ in the same way, it is clear that the resulting energy momentum tensors will have the same form, despite the different definitions of the electromagnetic potentials in the non-vortical and the vortical theories. Since the variables ξ, η do not enter (2) explicitly, they do not appear explicitly in the energy momentum tensor.

I take this opportunity to mention that the Schrödinger form of the non-vortical theory[3] is contained in the similarity theory of relativity, the variational principle being constructed in terms of the curvature scalar of a general symmetrical similarity tensor $S_{\sigma\tau}$. The details will shortly appear in *Physical Review*.

Colour in Electron Microscopy

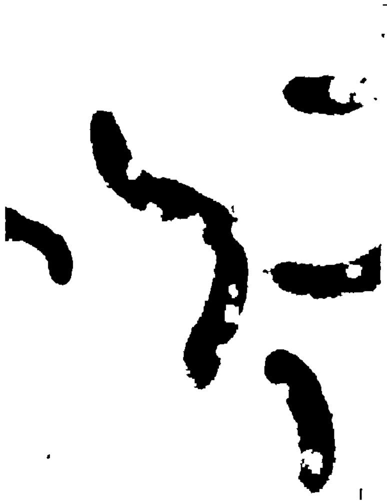
THE wave-length of the beam of an electron microscope, compared with visible light, is the property akin to colour. The beam is 'monochromatic' and it is standard practice to maintain it so within very narrow limits. The wave-length for electrons, in terms of their velocity expressed in electron volts, is given by the equation $\lambda = \sqrt{(150/V)}$ Angstrom units, where λ is the wave-length and V is the voltage accelerating the electrons. The 'colour' (wave-length) of the electron beam is varied by varying the voltage accelerating the electrons.

The image produced by the electron microscope is somewhat similar to a radiograph. The light and shade depend on the difference in the scattering and absorption of the beam by different parts of the specimen, which in turn depend on the wave-length. This is a function of the accelerating voltage, the thickness of the specimen, and the atomic numbers of the atoms composing the specimen.

The electron micrographs of the same specimen taken with electron beams of 25 kV. and 75 kV., respectively, show different detail and a certain amount of overlap. The internal detail in the higher-voltage picture shows up very well ; but very little is seen in the lower-voltage picture (see Figs. 1 and 2). The contrast of some low-density detail outside the bacteria which can be distinguished in the lower-voltage micrograph is reduced to such an extent as to render it nearly invisible in the higher-voltage picture. The similarity between micrographs taken at various voltages and X-ray pictures taken at various voltages, which is the basis of colour radiography introduced by Donovan[1,2], is obvious.

Colour electron microscopy involves the use of electron beams of two or more different voltages, and produces images in which colour is used to differentiate structure. Electron micrographs of the specimen are taken at two or more voltages (wave-lengths) selected to give the desired contrast. The images thus produced are each tagged in a visible colour such as red, green and blue, for a set of three electron micrographs, and are combined by optical superimposition or other means to form a colour electron micrograph. Such a composite colour picture shows not only variations in density but also variations in colour. Different colours in the final micrograph represent varying distribution of materials in the specimen absorbing or scattering at one or another of the wave-lengths (voltages) selected. In simplified effect, this method attempts to translate them into visible colours such as are seen in stained material used in light microscopy.

The easiest procedure is to treat the two or more electron micrographs taken at different voltages (wave-lengths) as separation negatives are in colour photography. A composite colour micrograph is assembled instantaneously by projecting in register the electron micrographs on to a viewing screen through suitable colour filters, or by means of viewing devices such as the chromoscope or 'Kromskop'. Permanent colour composite electron micrographic prints can be made with a modification of the 'Trichrome Carbro' process. Colour transparencies are made by photographing, serially and in register, the electron micrographs taken at the various voltages through appropriate colour filters on to the same frame of a colour photographic film.



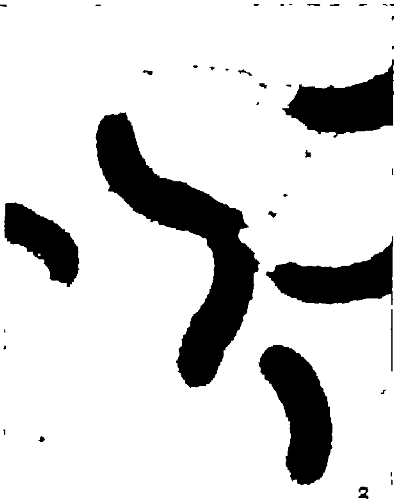


Fig. 1. Electron micrograph taken at 75 kV. Internal detail shows up, but external detail is practically invisible

Fig. 2. Electron micrograph taken at 25 kV of same specimen as Fig. 1. Internal detail shows up poorly, but external detail, such as flagella, shows up well

Satisfactory results can be obtained by using two voltages and two colours

Shadow-casting techniques are very popular in electron microscopy; they give a three-dimensional effect. The great defect of shadow casting is that only an outline of the organism shows and no internal structure is apparent. The electron microscope is capable, however, of showing great depth of focus and internal structure. A pseudo depth effect can be produced by careful choice of colours; red stands out, blue is recessive. This, allied to true stereoscopic electron microscopy, should produce very satisfactory stereoscopic electron micrographs.

We wish to thank Dr. F. T. Perkins and Dr. N. W. Preston, of the Department of Bacteriology, University of Manchester, and Messrs. Metropolitan-Vickers, Ltd., for their help.

A Genetical System admitting of Two Stable Equilibria

It has long been known that, in a population where different genotypes possess different selective advantages, it is possible for balanced polymorphism to exist. That is to say, there is an equilibrium between the proportions of different genotypes which is stable under random mating with differential viability and fertility. I do not know, however, whether any case has been recognized in Nature, or discussed theoretically, in which it is possible for two distinct non-trivial stable equilibria to exist. (A trivial equilibrium is an extreme case when, for example, some genes or genotypes are unrepresented in the population, and is of little interest.) It may therefore be of some theoretical value to construct a genetical system admitting of two distinct stable states of balanced polymorphism.

Analogy with electrical and mechanical oscillating systems suggests that the necessary degree of complexity may be achieved by a system composed of two 'coupled' sub-systems, possessing sufficiently unlike properties. Now the random mating of the sexes can be regarded as an interaction between two sub-populations. It is therefore natural to inquire whether a population in which the same genotypes have different viabilities in the two sexes is one admitting of a multiplicity of distinct equilibria. This expectation is verified. It is easy to specify a theoretical population involving three genotypes *AA*, *Aa* and *aa* with selective advantages different within and between sexes, which has three equilibria, of which two are stable and the third unstable. For example, with the scheme of viabilities:

	AA	*Aa*	*aa*
Females	0·50	1·00	0·50
Males	2·15	1·00	2·15

we obtain three equilibria characterized as follows for gene ratios in the two sexes and for stability:

Gene ratio (*A* : *a*)

Equilibrium state	In females	In males	Character
I	0·582	0·339	Stable
II	1·000	1·000	Unstable
III	1·718	2·931	Stable

I will give elsewhere a brief discussion of systems of this type. It is shown that they may possess (*a*) no non-trivial equilibrium state; or (*b*) a unique non-trivial equilibrium which may or may not be stable; or (*c*) three non-trivial equilibria, of which as many as two may be stable, the third being unstable.

All the possibilities relating to the case of three equilibria, and the necessary conditions on the viabilities, have not been exhaustively explored numerically, but their complete examination would present no great difficulty. The analysis suggests that a necessary condition for the existence of three equilibria is that, in at least one sex, at least one homozygote must be at an advantage relative to the heterozygote. It suggests further that the difference in viability between homozygotes and the heterozygote is required to be in opposite senses in the two sexes.

Origin and Development of Axillary Buds in Jute (*Corchorus capsularis*)

BRANCHING characteristics of the vast majority of plants are not a desirable character in a fibre crop like jute. Some foreign varieties of *Corchorus capsularis* like Halmahera, Jap Red and Jap G, unlike the Indian varieties, do not usually branch, as the axillary buds are normally absent in the axils of the leaves. These varieties supply the gene for non-branching character to be incorporated in the high-yielding Indian varieties. Though the anatomy of normal jute plant has been investigated in detail by Kundu[1,2], the organization of the shoot apex in the non-branching plants requires study, to find whether the absence of axillary buds is merely due to dormancy or complete absence of bud meristem in the axils of leaves. Such a study will doubtless help in rigid selection for non-branching varieties. A comparative developmental anatomy of four varieties of *Corchorus capsularis*, *D*154 (a branching variety), Halmahera, Jap Red and Jap G (non-branching varieties), was taken up in order to get precise information about the nature of non-branching character.

In the branching variety, *D*154, buds develop from a portion of apical meristem detached in the axils of leaves during vacuolation and growth, as described by Wardlaw in *Matteuccia*[3] and found in a great number of plants[4,5] (Fig. 1). Such a detached meristem can be seen as 'shell zone'[6] quite early, in the axil of the third leaf primordium. This zone enlarges by further divisions and emerges out in the axil of the sixth primordial leaf (Fig. 3). Its further development and size are determined by time of sowing, spacing and other factors. In the non-branching varieties (Halmahera, Jap Red and Jap G) 'shell zone', active or dormant, is completely absent (Fig. 2), except in some cases, where buds develop at irregular intervals and their development is similar to those in *D*154. Unless they are stimulated to grow by insect or accidental damage to the main apex, these few buds remain inconspicuous and usually do not develop any further. Some tips do not show axillary buds at all, but the possibility of development of buds at still earlier or later stages cannot be excluded.

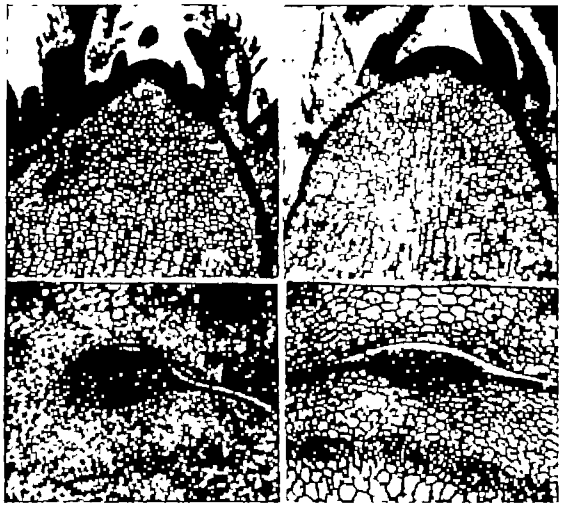

Fig. 1. L.S. of stem tip of *D*154 showing two shell zones and a portion of axillary bud
Fig. 2. L.S. of stem tip of Halmahera showing absence of shell zones
Fig. 3. T.S. of stem tip of *D*154 showing origin of axillary bud
Fig. 4. T.S. of stem tip of Halmahera showing origin of extra-axillary bud

Extra-axillary buds develop irregularly in the three non-branching varieties, but more frequently in Halmahera. In the development of extra-axillary buds, a definite zone of detached meristem exists as usual from early stages. But some previously vacuolated cells of the axis above the axil which are in continuation with the detached meristem resume meristematic activity and are responsible for the development of bud proper (Fig. 4). In all these cases the development of provascular tissues in the bud is acropetal. The development of buds is possibly checked in the non-branching varieties by production of a sort of heteroauxin[7], which is controlled by a single recessive gene; but its expression is not complete in these varieties, as is evident from the occasional production of buds.

Details will be published elsewhere.

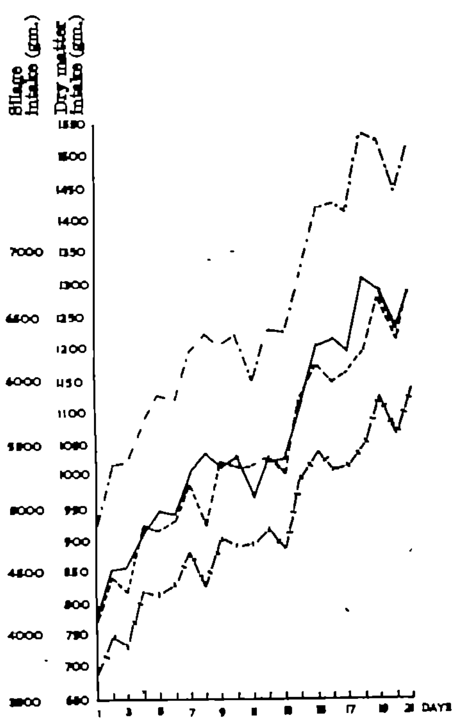
Effect of the Percentage of Dry Matter in the Diet on the Dry-Matter Intake in Ruminants

IN the course of some experiments with beef cattle, swedes and grass silage were fed, and it was observed that the appetite of the cattle, in terms of daily intake of dry matter, appeared to be inversely proportional to the percentage of moisture in these feeding-stuffs.

In order to obtain further data on this point, two sheep were fed to appetite with grass silage containing 22·66 per cent of dry matter, and a second pair of sheep received silage, from the same source, to which 300 c.c. of water had been added per kilogram of the original silage. The percentage of dry matter of this watered silage, as fed, was 16·85 per cent. All sheep were fed to appetite, and the average weight of silage eaten daily by each pair of sheep has been plotted on the accompanying graph together with the average daily dry-matter intake.

It will be noted that the weight of the daily intake of silage varied very little between the two groups of sheep, but there was a wide difference in the daily intake of dry matter, the figure being consistently higher for the sheep on the silage with a higher dry-matter percentage.



Daily intake of silage: ———, 22·66 per cent dry matter silage; – – – –, 16·85 per cent dry matter silage.
Daily intake of dry matter: —.—., from 22·66 per cent dry matter silage; —ɪ—ɪ, from 16·85 per cent dry matter silage

Although the experimental period lasted for only three weeks, these results confirm that when ruminants are fed twice daily on a diet consisting solely or mainly of succulent foods, the daily intake of dry matter is directly related to the percentage of dry matter in the diet. It follows that if ruminants are fed solely or mainly on succulent foods, maximum performance can only be expected if the dry-matter percentage of the succulent foods is maintained at a sufficiently high level to ensure that the dry-matter percentage in the diet as a whole does not fall below some critical figure—probably somewhere between 20 and 25 per cent—but this point requires further investigation.

A fuller report of this and the experiments leading up to it is in preparation for publication.

Chromosomes of the Indian Water Buffalo

The number of chromosomes of the water buffalo (*Bubalus bubalis* L.) is a controversial issue (the names *Bubalus bubalus* L. and *B. buffelus* L. are synonyms of *B. bubalis* L.). Pchakadze[1] stated that it is $2n = 56$. Makino[2], on the contrary, reported the diploid number of chromosomes to be 48. In view of this disagreement, it was considered worth while to study the number of the Indian water buffalo.

Testicular materials, obtained by castration from 1-yr., 2½-yr. and 6-yr. old buffaloes of the Murrah breed, were fixed in Belling's modification of Nawaschin mixture, sectioned at 15 μ in thickness and stained in iodine crystal violet after overnight premordanting in 1 per cent chromic acid.

Examination revealed that the materials taken from animals aged 2½ yr. and 6 yr. were not suitable for spermatogonial chromosome count. A few good metaphase plates were, however, seen in these tissues. A large number of dividing cells were obtained in the material taken from the 1-yr. old animal. The study of the spermatogonial metaphase (Fig. 1) showed that the diploid number of chromosomes is 48. There are two types of chromosomes in respect of the position of the centromere: the first comprises four pairs with median or submedian centromere, and the second twenty pairs of rod-shaped chromosomes with terminal or nearly terminal centromere. Among the first group, there are two pairs of *J*-shaped chromosomes which are the longest in the complement. The pair next in size is also *J*-shaped, but its long arm is slightly smaller than that of the longest one, while the size of the short arm is the same as that of the longest pair. The fourth pair is a *V*-shaped one with equal arms. Among the rod-shaped chromosomes, the *X*-chromosome was found to be the longest and the *Y* seemed to be one of the smallest. Contrary to Makino, who observed that the *X*-chromosome was more deeply stained than others, no differential staining behaviour was noted in this chromosome. The number of chromosomes was also verified from the polar view of metaphase II, where there were 24 chromosomes of different sizes (Fig. 2). Our observation is in agreement with that of Makino.

Micro-forceps and Micro-scalpels

Some convenient glass micro-forceps are shown in Fig. 1. Type I are opened by their own resilience and closed by means of a tube fitting around them. In type II the reverse action is shown, closing being effected by resilience and opening by the force of a ball and rod. The two branches of the forceps are fixed in a tube of 1·5 mm. diameter, which is mounted on a de Fonbrune micromanipulator. A second tube, enclosing the first tube, can be made to slide around the branches of the forceps, operating it by means of a piston and a syringe. The closing movement is smooth and can be controlled within the limits of a few microns. The points remain exactly opposed.

The points of type II are useful for holding very fragile objects. Type I can hold microscopical objects of various kinds, since the points can be modified to suit several purposes.

Six modifications are shown in photograph III. The points shown are, respectively, in the form of: (1) strong pincers; (2) fine pincers; (3) eyelets (Schouten type[1], diameter 7 and 20 microns, for isolating micro-organisms); (4) ball and cup (de Fonbrune type[2]); (5) a tong-like structure; and (6) pipettes (one point is filled with fluid).

The following possible applications of these forceps may be suggested: experiments on single fibres (for example, muscle, collagen, textile fibres); clamping capillaries, partly or completely; injecting two fluids in the same place; holding small quantities of different materials (for example, radioactive chemicals); micro-dissection.

Any one of the instruments illustrated can be made with the de Fonbrune microforge within a quarter of an hour.

The micro-scalpels shown in Fig. 2 are made essentially by breaking glass rods. They have cutting edges all round, the sharpness of which is generally sufficient to cut bacteria.

A Test for Montmorillonite

It has been shown that montmorillonite saturated with small ions, for example, lithium, is difficult to rehydrate after being dried at moderate temperatures[1-3]. This behaviour has been found to be confined to montmorillonite and forms the basis of a new test which enables the mineral to be easily distinguished from the other common montmorillonoids[4].

The hysteresis observed on drying is due to a decrease of the internal surface, which takes place in a random way and leads to the phenomenon of random inter-stratification in the re-solvated mineral. In consequence of this, the dried mineral also shows a marked decrease in exchange capacity due to the decreased rate of exchange of the interlamellar ions. The test may therefore take a number of forms, any of which may be used to identify montmorillonite.

In practice, lithium montmorillonite has been found to show the greatest effect. If the sample is either in the form of oriented flakes or powders, satisfactory saturation with lithium ions may be obtained by three washings with 3 *M* lithium chloride, the excess salt being removed with warm 80 per cent alcohol. By means of this procedure the mineral remains aggregated and the flakes retain their structure.

Lithium montmorillonite treated with glycerol, after being dried at 100° C., shows a rational series of reflexions corresponding to *d*(001) of 17·7 kX. on X-ray analysis. If the drying is carried out at 200° C., a markedly decreased rate of uptake of glycerol is observed and the X-ray diffraction pattern shows an irrational series of reflexions that would be expected for a random mixture of spacings of 9·4 and 17·7 kX. in equal proportions[5]. Heating to 300° C. leads to a rational series of reflexions corresponding to $d(001)$ of 9·4 kX.

Lithium montmorillonite dried at 200° C. shows a decreased exchange capacity to ammonium ions at *p*H 7, when compared with samples dried at 70° C. Wyoming bentonite showed a change from 90 m.equiv./100 gm. to 3 m.equiv./100 gm. Differential thermal analysis on lithium montmorillonite dried at 200° C. and rehydrated at 50 per cent relative humidity showed that the endothermic peak between 100° and 200° C., due to sorbed water, was greatly decreased when compared with samples dried[5] at 70° C.

These changes of internal surface on drying at 200° C. were not observed with authentic samples of beidellite (Black Jack Mine)[6], saponite (Cathkin Hill)[7], hectorite (California)[8] and two nontronites when saturated with lithium. It appears, therefore, that this decrease in internal surface takes place only when the mineral is dioctahedral and the charge in the silicate sheets is due predominantly to substitution in the octahedral layers. The test thus provides a useful method of distinguishing between the end members of the montmorillonite-beidellite series, which is a difficult procedure in the case of impure samples.

Grateful acknowledgment is made to the British Museum (Natural History), Geological Survey, and the Fullers Earth Union, Ltd., for gifts of minerals.

Minimum Phosphate and Magnesium Requirements of Nitrifying Bacteria

THE nutrient requirements of the autotrophic nitrifying bacteria are simple, but among the elements which seem to be essential for them are phosphorus and magnesium. Bömeke[1] reported that *Nitrobacter* would not grow in media from which either phosphate or magnesium was omitted; and *Nitrosomonas* would not grow in medium with magnesium omitted. Wimmer[2] found that phosphate was necessary for the growth of both organisms, but the minimum requirement was only 0·02 mgm. phosphorus per litre for both *Nitrobacter* and *Nitrosomonas*.

To find the minimum requirements of nitrifiers for these two elements, pure cultures were grown in 5-ml. liquid medium in test-tubes covered with aluminium caps. The control medium contained $M/1,000$ phosphate and $M/1,000$ magnesium sulphate. A series of transfers was made on media from which either the phosphate or the magnesium was omitted. The bacteria used were: a strain of *Nitrosomonas europaea* from Denmark[3] and a strain of *Nitrobacter winogradskii* from Ampthill, Beds[4]. A drop from a Pasteur pipette was used as the inoculum, so that the dilution at each transfer was about a hundred times.

Phosphate. The *Nitrosomonas* survived no less than eleven successive transfers on to medium with phosphate omitted; but no special steps were taken to purify the medium from every trace of phosphate, so a very small amount (too small to give the usual drop reaction for phosphate) may have been present. In any event, the amount carried over in the inoculum was very small; after three transfers, only a fraction of a microgram would be carried over. *Nitrobacter* ceased to oxidize nitrite in the second transfer, but the bacteria survived, as transfers back on the control medium were normal. On the second transfer, the theoretical amount of phosphorus carried over in the inoculum would correspond to about 0·003 mgm. per litre.

Magnesium. Both species continued to oxidize ammonia or nitrite up to the fourth successive transfer on to medium with magnesium omitted. By this transfer, the theoretical amount of magnesium carried over in the inoculum would be about 0·0002 mgm. per litre. Both species survived, as transfers back to control medium grew.

Sir Jack Drummond, F.R.S.

THE news of the tragic death of Sir Jack Drummond came as a severe shock to his many friends in America. Only after the initial paralysing numbness associated with the sporadic news flashes of his murder had worn off could the enormity of this crime be appreciated. Although the loss to the scientific world has been great, a deep feeling of the personal loss of a friend has been experienced by many of us in Canada. Over the years Jack Drummond has made numerous Canadians his associates. His interest and hospitality was extended to many junior men of science, and all of us will remember the impact of his personality as he blended the science of nutrition and the art of entertainment into a formula as palatable as his Englishman's food. Perhaps no one has done so much to help so many Canadian medical research students attain a balanced perspective of scientific life in England. To many of us the pleasure of informal evenings, and the charm of Drummond as a host, will remain as our most vivid memory of a man who was truly more than a great man of science.

FORTHCOMING EVENTS

Tuesday, December 30—Friday, January 2

SCIENCE MASTERS' ASSOCIATION (in the Chemistry Department, Royal College of Science, Imperial Institute Road, London, S.W.7).—Annual Meeting: "Science in the Service of the Community".

Friday, January 2

INSTITUTION OF MECHANICAL ENGINEERS (joint meeting with the INDUSTRIAL ADMINISTRATION AND ENGINEERING PRODUCTION GROUP, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Capt. G. C. Adams: "Principles and Practice Governing Interchangeability and the Specification of Manufacturing Limits of Size as influenced by Statistical Considerations".

APPOINTMENTS VACANT

SENIOR LECTURER IN PHYSICS and a SENIOR LECTURER IN PHYSICAL CHEMISTRY (with a good honours degree in physics or chemistry respectively and, if possible, experience in teaching, industry and research)—The Principal, Acton Technical College, High Street, Acton, London, W.3 (January 3).

LECTURER IN PHYSIOLOGY—The Registrar, The Medical School, Birmingham 15 (January 10).

GRADUATE (male) IN BOTANY or AGRICULTURE in the Technical Advisory Section—The Director, Sports Turf Research Institute, St. Ives Research Station, Bingley, Yorks (January 15).

SENIOR ORGANIC CHEMIST to the Division of Biochemistry and General Nutrition, C.S.I.R.O., at the central laboratories in the University of Adelaide, to work on general problems involved in the introduction of isotopic carbon, nitrogen, etc., into organic compounds—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment 4078 (January 17).

CHAIR OF FUEL TECHNOLOGY—The Registrar, The University, Sheffield (January 31).

LECTURER IN BIOCHEMISTRY—The Secretary, Queen's University, Belfast (February 25).

ASSISTANT EXPERIMENTAL OFFICERS IN THE INSTRUMENTATION DEPARTMENT of the Royal Aircraft Establishment, Farnborough, for design and development of equipment for measurements in aeronautical research: ELECTRICAL ENGINEER or PHYSICIST for work on electronic circuits, and an ELECTRICAL or MECHANICAL ENGINEER for work on electro-mechanical instruments—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.472/52A.

ASSISTANT LECTURER (Grade B) IN CHEMISTRY at the Wolverhampton and Staffordshire Technical College—The Clerk to the Joint Education Committee, Education Offices, North Street, Wolverhampton.

HEAD OF THE SCIENCE DEPARTMENT of the Ewell Technical College—The Chief Education Officer, County Hall, Kingston-upon-Thames, Surrey.

PHYSICAL CHEMIST (with research experience) to investigate certain biophysical aspects of flour milling, and a CHEMIST for research on flour quality—The Director, Research Association of British Flour Millers, Cereals Research Station, Old London Road, St. Albans, Herts.

PHYSICIST or ENGINEER IN THE INSTRUMENTS AND AIR PHOTOGRAPHY DIVISION of the Royal Aircraft Establishment, Farnborough, for research and development on analogue computers, servo-mechanisms and similar precision electro-mechanical equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.312/52A.

Andrade, Prof. E. N. da C. : Viscosity and Thermal Conductivity of Liquid Argon, 794
Andreae, W. A. : Effect of Scopoletin on Indoleacetic Acid Metabolism, 83
Andrews, E. D. (Anderson, J. P., and) : Response to Vitamin B_{12} of Grazing Cobalt-deficient Lambs, 807
Andrews, W. H. : Appointed agricultural officer, Tanganyika, 1003
Anger, H. O. : Use of a Gamma-Ray Pinhole Camera for *in vivo* Studies, 200
Anglo-Saxon Petroleum Co., Ltd. : Gift of £2,700 annually to University College, London, for scholarships in chemical engineering, 829
Anlansson, Gunnar, and Steiger, Naftali : Microradiography with Alpha-Rays, 201
Anti-Locust Research Centre, London : Appointment of Dr. T. H. C. Taylor as deputy director (Senior Principal Scientific grade of the Scientific Civil Service), 1049
Appleton, Sir Edward : Elected president of the British Association for the Advancement of Science for 1953, 440 ; work of, 440
Apps, R. P. : Appointed scientific officer, Royal Observatory, Hong Kong, 269
Arcetri Astrophysical Observatory : Papers from the, 1100
Archaeology at Athens, British School of : Annual Report for the Session 1950–51, 269
Arctic Institute of North America (McGill University and the) : Fellowship and Scholarships for work on Arctic or Sub-Arctic Research, 695
Arden-Close, Sir Charles : *Death* of, 1098
Aribisala, R. : Appointed an agricultural officer, Nigeria, 60
Arid Zone Research, Advisory Committee on : Meeting in London, 1103
Arif, Dr. A. G. : Botany of Flax, 557
Arisz, Prof. W. H. : Transport of Substances through the Tentacles of Leaves of *Drosera capensis* L., 932
Armour, C. J. (Thompson, H. V., and) : Rabbit Repellents, *correction*, 442
Army Council : Appointment of H. A. Sargeaunt as scientific adviser to the, 61
Arnold, R. M. : Appointed deputy director (livestock), Jamaica, 608
Arnott, G. W. : Appointed agricultural chemist, Federation of Malaya, 61
Artedi, Peter : Biography of (Dr. O. Walde and Prof. H. Engel), 17
Arthington, W. (Hulme, Dr. A. C., and) : New Amino-Acids in Young Apple Fruits, 659
Arts, Royal Society of : Albert Medal awarded to Sir Frank Whittle, 19
  Election of H.R.H. The Duke of Edinburgh as president, 829
  Centenary Number of the *Journal*, 1048
Asdell, Prof. S. A. : Fertility, 231
Asfour, W. R. : Appointed agricultural superintendent, British Guiana, 564
Ashbridge, Sir Noel : Television Development, 136
  Applications of Communication Theory, 1051
Ashby, Dr. Eric : The University Training of a Botanist, 770, 773
Ashley, P. G. : Insulation of Electrical Equipment, 1006
Ashmore, Dr. P. G. (Chanmugam, J., and) : The Hydrogen–Oxygen Reaction Sensitized by Nitrosyl Chloride, 1067
Ashwell, G. E. : Encyclopedia on Cathode-Ray Oscilloscopes and their Uses, *review*, 684
Askew, R. : Education of the Deaf, 525
Aslib : Twenty-seventh Annual Conference, 61
  Annual Report for 1951, 268
  Conference on the Significance of Information in Present-Day Industrial Society, 698
Asquith, Dr. R. S., and Speakman, Prof. J. B. : Chemical Mechanism of Permanent Set, 798
Associated Portland Cement Manufacturers, Ltd. : New Research Laboratories at Stone opened by the Rt. Hon. D. McA. Eccles, 270
Astbury, Prof. N. F. : Micro-Magnetic Variations during the Solar Eclipse of February 25, 1952, 68
Astbury, Prof. W. T. : The Structure of Proteins, 53
Astronautical Federation, International : Election of Officers, 1053
Astronomical Union, International : Eighth General Assembly, 60, 229, 785
  Symposium on Stellar Evolution, 786
  Symposium on the Astrometry of Faint Stars, 786
  Symposium on Instruments, 786
Astrup, Dr. Tage, and Stage, Agnete : Isolation of a Soluble Fibrinolytic Activator from Animal Tissue, 929
Astrup, Dr. Tage, and Sterndorff, Ida : Fibrinolytic Activity of Tissue Extracts and of Trypsin, 981
Atkinson, E. B. : Plasticity of Materials, 876
Atkinson, J. R. : Appointed senior lecturer in natural philosophy at the University of Glasgow, 19
  Photodisintegration, 514
Atkinson, R. E. H. : Appointed agricultural officer, Uganda, 1003
Atlas, D. : Application of Radar to Meteorology—Rain Measurements, 1004
Atomic Energy Research Establishment : Course of instruction at the Isotope School of Harwell in the technique of handling and using Radioactive Isotopes, 694
Attle, E. : Awarded a Postgraduate Research Scholarship by Courtauld's Scientific and Educational Trust Fund, 346
Attwood, C. : Advanced Five-Figure Mathematical Tables, *review* by J. H. Pearce, 641
Aubert, Prof. G. : Desert Research, 301
Auclair, J. L., and Maltais, J. B. : Occurrence of Gamma-Amino-Butyric Acid in Extracts of *Pisum sativum* (L.) and in the Honeydew of *Myzus circumflexus* (Buck.), 1114
Audus, Prof. L. J. : The University Training of a Botanist, 770, 773
  Fate of Sodium 2,4-Dichlorophenoxy-ethyl-sulphate in the Soil, 886
Austin, C. R. : The 'Capacitation' of the Mammalian Sperm, 326
Austin, C. R., and Braden, A. W. H. : Passage of the Sperm and the Penetration of the Egg in Mammals, 919
Austin, Mrs. P. M. : Application of Radar to Meteorology—Precipitation Mechanisms, 1004
Australian Academy of Science : An, 549
Australian Chemical Institute, Royal : H. G. Smith Memorial Medal awarded to Prof. R. J. W. LeFèvre, 1049
Australian Chemist : H. G. Smith (1852–1924), a Pioneer, 736
Australian Department of Supply : Appointment of Dr. C. F. Bareford as chief superintendent of the Long Range Weapons Establishment, 1047
Australian and New Zealand Association for the Advancement of Science : Meeting at Sydney, 189
Ayers, J. (Klotz, I. M., and) : Physical Chemistry of Proteins, 519
Aylward, Dr. Francis : Unusual Foods for Human Consumption, 1050
Ayres, Audrey, and others : Enzymic Degradation of Pectic Acid and the Complex Nature of Polygalacturonase, 834

BABAD, J., and others : An Antifungal Polypeptide produced by *Bacillus subtilis*, 618
Bacharach, A. L. : Analysis by Diffusion, *review*, 5
  Enzymes, *review*, 257
  Unusual Foods for Human Consumption, 1050
Back, A., and others : Acquired Resistance to Colchicine in a Strain of *Trichomonas vaginalis*, 930
Bacteriology (Applied), Society for : Summer Conference in Cambridge, 444
  Discussion on Farm Water Supplies, 1107
Badcock, Ruth M. : Observation of Egg-laying under Water of the Aerial Insect *Hydropsyche angustipennis* (Curtis) (Trichoptera), 40
  Appointed a lecturer in biology at the University College of North Staffordshire, 653
Baddiley, Dr. J. : Pyridoxal Derivatives in Transamination, 711
Baddiley, Dr. J., and others : A New Method for Acetylating Proteins, 968
Badreldin, Prof. A. L., and Ghany, M. A. : Adaptive Mechanisms of Buffaloes to Ambient Temperature, 457
Bagnold, Dr. R. A. : Desert Research, 301
  Biology and Productivity of Hot and Cold Deserts, 951
Bailey, Dr. A. E. : Applications of Communication Theory, 1052
Bailey, Sir Donald : Promoted Deputy Chief Scientific Officer in the Scientific Civil Service, 309
Bailey, Sir Edward : Hugh Miller, 1802–56—Commemoration at Cromarty, 790
Bailey, Dr. K. : The Structure of Proteins, 55
Bailey, Dr. K. (Tsao, T.-C., and) : Physical Chemistry of Proteins, 519
Baker, Prof. J. F. : Awarded the Ewing Gold Medal of the Institution of Civil Engineers, 1100
Baker, Prof. W. : Substances naturelles de synthèse, Vol. 3, *review*, 817
Baker, Dr. W. G., and Martyn, Dr. D. F. : Conductivity of the Ionosphere, 1090
Baker Perkins, Ltd., Peterborough : Gift of a machine to the Department of Leather Industries in the University of Leeds, 143
Balachowsky, Prof. A. S. : Biology and Productivity of Hot and Cold Deserts, 952
Balashek, Dr. S. : Applications of Communication Theory, 1052
Baldamus, Dr. W. : Incentives and Size of Industrial Plant in Great Britain, 112
Baldwin, Prof. E. H. F. : Awarded the European Cortina-Ulisse Prize for 1952, 605
Ballantyne, A. O. : Awarded a Postgraduate Scholarship in Husbandry by the Department of Agriculture for Scotland, 784
Ballard, L. A. T. : Coloured 'Perspex' for Darkroom Lights, 840
Bamford, Dr. C. H. : The Structure of Proteins, 54
Bamford, Dr. C. H., and Barb, W. G. : Reactivity of Free Radicals, 821
Bannister, D. W. : Awarded a Postgraduate Research Scholarship by Courtauld's Scientific and Educational Trust Fund, 346
Bannister, Dr. F. A. : Clay Minerals, *review*, 337
  Appointed keeper of the Department of Mineralogy at the British Museum (Natural History), 782, 1000 ; work of, 1000
Bannister, Prof. F. K. : Appointed to a newly created chair of thermodynamics in the Department of Mechanical Engineering in the University of Birmingham, 142 ; work of, 142
Baptist, Dr. N. G. : Amino-acids in Legumes, 76
Baptista, A. (Palacios, Prof. J., and) : Demonstration by Radioactive Tracers of the Adsorption of Cations by Metals, 665
Baranov, Dr. V. : Prospecting by Geophysical Methods, 230
Barb, W. G. (Bamford, Dr. C. H., and) : Reactivity of Free Radicals, 821
Barber, Richard, and others : Hypotensive Alkaloids of *Veratrum album*, 932
Barbosa, H. : New Research Techniques in Physics, 700
Barbu, E., and Joly, M. : Physical Chemistry of Proteins, 518
Bareford, Dr. C. F. : Appointed chief superintendent of the Long Range Weapons Establishment of the Australian Department of Supply, 1047 ; work of, 1047
Barer, Dr. R. : Interference Microspectroscopy, 29
Barkas, Dr. W. W., and Christensen, G. N. : Plasticity of Materials, 876
Barker, Sir Ernest : Principles of Social and Political Theory, 1
Barker, R. H. : Applications of Communication Theory, 1051
Barlow, F. (Hadaway, A. B., and) : Inactivation of DDT by Soils, 762
Barnard, Chester I. : The Rockefeller Foundation, a Review for 1950 and 1951, 721, 963
Barnes, Dr. B. : Retirement as head of the Department of Biology at Chelsea Polytechnic, 870 ; work of, 870
  Classification of the Fungi, 997
Barrer, Prof. R. M. : Chemistry in Aberdeen, 741
Barrett, Prof. C. S. : Measurement and Importance of Elastic Properties of Metals, 529
Barrett, K. E. J. (Waters, Dr. W. A., and) : Reactivity of Free Radicals, 820
Barrington, Prof. E. J. W., and Matty, A. J. : Influence of Thiourea on Reproduction in the Minnow, 105
Barron, S. : C. T. R. Wilson and the Cloud Chamber, 404
Barrow, Hepburn and Gale : Gift of equipment to the Department of Leather Industries in the University of Leeds, 143
Bartlett, Sir Frederic : Awarded a Royal Medal for 1952 of the Royal Society, 870, 947 ; work of, 947
Barton, G. M., and others : Paper Chromatography of Phenolic Substances, 249

NAME INDEX

Barton-Wright, Dr. E. : Third European Brewery Convention, *review*, 901
Bateman, A. J. : Trimorphism and Self-incompatibility in *Narcissus*, 496
Bateman, L., and others : Reactivity of Free Radicals, 820
Bates, Prof. D. R. : Electrical Discharges in Gases, 603
Bates, Lieut.-Colonel R. S. P., and Lowther, E. H. N. : Breeding Birds of Kashmir, *review*, 511
Baud, Paul : Traité de chimie industrielle, quatrième édition, Tomes 1–3, *review* by H. M. Langton, 4
Bawden, F. C. : Plant Viruses and Virus Diseases, third edition, *review* by Dr. K. M. Smith, 1087
Bawn, Prof. C. E. H. : Radiation Chemistry, 194
  Autoxidative Reactions—their Chemistry, Mechanisms and Catalysis by Metal Salts, 653
  Reactivity of Free Radicals, 820
Baxendale, J. H., and Magee, J. : Reactivity of Free Radicals, 821
Bayle, Dr. Henri : Fertility, 232
Beale, B. J. : Awarded a Clayton Fellowship of the Institution of Mechanical Engineers, 229
Beaton, A. : Appointed assistant conservator of forests, Uganda, 1003
Beaver, Sir Hugh : Appointed a member of the Advisory Council for Scientific and Industrial Research, 829
Becker, Ernest I. (Goldman, Martin, and) : A Novel Synthesis for Aroylacrylic Acids, 35
Becking, Prof. L. G. M. Baas, and Everson, R. G. : Early Effects of Growth Substances, 1019
Becquerel, Antoine Henri (1852–1908), 1001
Bedford, L. H. : Fellowship of the City and Guilds of London Institute conferred on, 406
Bedford College for Women : Celebration of the reconstruction of War-damaged Buildings, 564
Bedson, Prof. S. P. : Title of professor emeritus in bacteriology in the University of London conferred on, 228
Beebe, Dr. William : To retire with the title of director emeritus of the Department of Tropical Research in the New York Zoological Park, 345
Beer, Dr. G. R. de : Embryos and Ancestors, revised edition, *review* by Prof. S. Zuckerman, 5
  Elected correspondent of the Section of Anatomy and Zoology of the Paris Academy of Sciences, 956
Beijer, W. H. : Methane Fermentation in the Rumen of Cattle, 576
Beilby Memorial Fund : Awards, 739
Bélanger, Prof. Leonard F. : Improvements to the Melted Emulsion Technique of Autoradiography, 625
Belasco, Dr. J. E. : Characteristics of Air Masses over the British Isles, 27
Belavady, Miss Bhavani, and others : Biosynthesis of Vitamin C and a New Precursor, 545
Belcher, Dr. E. H. : Luminescence of Aqueous Solutions of Radioactive Isotopes and the Cerenkov Effect, 571
Bell, D. A. : Applications of Communication Theory, 1052
Bell, Dr. L. G. E. : Edmond About and the Technique of Freezing and Drying Tissues, 547
  Cooling Bath for Cytological Investigations, 719
Bell, Peter : The University Training of a Botanist, 772
Bell, W. (Blacet, F. E., and) : Reactivity of Free Radicals, 820
Belton, Dr. J. W. : Radiation Chemistry, 194
Bemis, A. C. : Application of Radar to Meteorology, 1004
Bendall, J. R. : Effect of the 'Marsh Factor' on the Shortening of Muscle Fibre Models in the Presence of Adenosine Triphosphate, 1058
Bender, Dr. R. S. : Medium-Energy Nuclear Physics, 349
Benedetti, Dr. S. de : New Research Techniques in Physics, 701
Bennet-Clark, Prof. T. A. : The University Training of a Botanist, 773
Bentley, Dr. J. A. : Text-Book of Plant Growth Substances, *review*, 510
Bentley, Miss L. E. : Occurrence of Malonic Acid in Plants, 847
Berg, Dr. W. F. : Applications of Photography to Research in the University, 879
Bergmann, Dr. Ernest D., and Sicher, Sarah : Mode of Action of Chloramphenicol, 931
Berl, W. G., and Dembrow, D. : Twin Flames, 367
Berlie, M. R., and LeRoy, D. J. : Reactivity of Free Radicals, 819
Bernaerts, M., and De Ley, Dr. J. : Microbiological Decomposition of Malto- and Lacto-bionate, 713
Bernal, Prof. J. D. : The Structure of Proteins, 55
Bernard, Prof. F. : Biology and Productivity of Hot and Cold Deserts, 952
Berndt, Ronald and Catherine : From Black to White in South Australia, *review* by D'Arcy Ryan, 551
Bernhard, W. : Electron Microscope Studies on Thin Sections of Human Erythrocytes, 359
Berrill, Prof. N. J. : The Living Tide, *review* by Dr. D. P. Wilson, 640
Berry, J. : Applications of Communication Theory, 1052
Berry, M. J. : Appointed assistant conservator of forests, Federation of Malaya, 1003
Bertazzoli, C., and others : Effect of Cortisone on the Blood Pressure of Normal Rats, 43
Besicovitch, Prof. A. S. : Awarded the Sylvester Medal of the Royal Society, 826, 948 ; work of, 948
Bessey, G. E. : Plasticity of Materials, 876
Beswick, G. R. : Awarded the President's Prize and the Electronic Measurements Prize of the British Institution of Radio Engineers, 308
Beurle, Dr. R. L. : Applications of Communication Theory, 1052
Bevan, P. A. T. : The British Contribution to Television, 137
Beveridge, E. (Walls, Dr. L. P., and) : Reduction of Nitrophenanthridinium Salts—Influence of Molecular Size on Trypanocidal Activity, 666
Bevington, J. C., and others : Self-branching of Vinyl Polymers, 1026
Bhargava, B. N. : A New Early-Morning Ionospheric Phenomenon, 983
Bhat, Dr. R. V., and Jaspal, Narendra S. : Pulps for Writing and Printing Papers from the Castor Oil Plant *Ricinus communis*, 28
Bhattacharya, P. (Dutt, M. K., and) : Chromosomes of the Indian Water Buffalo, 1129
Bhattacharyya, B. K., and Sengupta, P. : A New Route to Œstrone, 710
Bickel, Dr. A. F., and Kooijman, Dr. E. C. : Hydrogen Transfer by Thiols, 211
Bickley, Prof. W. G. : Tables of the Error Function and of its First Twenty Derivatives, *review*, 1089
Biddulph, Dr. R. : Applications of Communication Theory, 1052
Biek, L. : Technical Aids in Archæology, 909
Biggers, J. D. : Response of the Vaginal Epithelium of the Ovariectomized Mouse to the Systemic and Local Administration of Œstrone, 895
Biggs, Dr. Rosemary : Plasma Thromboplastin, 280
Bihar Academy of Agricultural Sciences : *Proceedings*, No. 1, 563
Billimoria, Dr. J. D. : Simple Analogues of Cortisone, 248
Binns, A. L. : Education of Africans in East and Central Africa, 399
  Education of the Deaf, 525
Biological Council : To become an advisory body to the Institute of Biology, 651
  Election of Officers, 651
Biological Sciences, International Union of : Meeting of the Executive Committee, 23
Biological Sciences, International Union of (Zoological Section) : Preparation of an Index of Zoologists, 189
Biology, Institute of : Discussion on Biology as a Career, 189
  Survey of Centrifuges and *p*H Meters, 229
  The Biological Council to become an advisory body to the, 651
  Freezing and Drying : Report of a Symposium held in June 1951, *review* by Dr. Geoffrey H. Bourne, 723
  Symposium on the Biology and Productivity of Hot and Cold Deserts, 951
Biology, Institute of, and others : Discussion on the Place of the Scientist in Civil Defence, 406, 957
Birch, S. F., and others : Thiaadamantane, 629
Bird, Lieut.-Colonel G. W. G. : Relationship of the Blood Sub-Groups A_1, A_2 and A_1B, A_2B to Hæmagglutinins present in the Seeds of *Dolichos biflorus*, 674
Bird Preservation, International Committee for (European Continental Section) : Fifth Conference, 97
Birk, Mrs. Yehudith (Bondi, Dr. A., and) : A Difference in *in vitro* Pancreatic Digestion between Animal and Plant Protein Feeds, 673
Birkbeck College, London : Appointment of Dr. W. S. Bullough to the University of London chair of zoology, 60, 142
Birkett, J. D. : Appointed director of veterinary services, Sierra Leone, 695
Birkinshaw, D. C. : The British Contribution to Television, 137
Bishop, G. R., and others : Evidence for the Polarization of the Protons produced in the D—D Reaction, 113
Bisset, Dr. K. A., assisted by Moore, F. W. : Bacteria, *review* by Dr. S. T. Cowan, 133
Blacet, F. E., and Bell, W. : Reactivity of Free Radicals, 820
Black, Dr. D. J. G., and others : 'Infra-Red' Brooding and the Crooked-Toe Problem in Chicks, 167
Black, Dr. W. A. P. : Unusual Foods for Human Consumption, 1050
Blackall, Eileen L., and Hughes, Prof. E. D. : *N*-Nitration and *C*-Nitration by the Nitronium Ion, 972
Blackett, Prof. P. M. S. : Appointed to the University of London chair of physics at the Imperial College of Science and Technology, 1003
Blackham, H. J. : Freedom and Responsibility, 217
Blackley, D. C. : Awarded a Postgraduate Research Scholarship by Courtauld's Scientific and Educational Trust Fund, 346
Blackman, Prof. G. E. (Robertson-Cuninghame, R. C., and) : Effects of Preliminary Treatment on the Subsequent Variation in the Resistance of *Lemna minor* to the Phytotoxic Action of 2 : 4 Dichlorophenoxyacetic Acid, 459
Blackwood, Miss B. M. : Archæology in Ecuador, *review*, 51
Blair, Dr. G. W. Scott : Relativity and Indeterminacy, 582
Blake, Sir John : Centenary of the Patent Office, 1044
Blakemore, Prof. F. : Appointed a member of the Agricultural Improvement Council for England and Wales, 348
Blakey, B. C. : Emulsions and Films, 234
Blakey, Dr. Frank A. : Mechanism of Fracture of Concrete, 1120
Blanc-Lapierre, Prof. A. : Applications of Communication Theory, 1053
Blayden, H. E., and others : Nature of the Solution obtained by Pyridine Extraction of Coal, 317
Blinks, Prof. L. R. (McClendon, Dr. John H., and) : Use of High Molecular Weight Solutes in the Study of Isolated Intracellular Structures, 577
Bloch, Prof. Felix : Awarded jointly with Prof. E. M. Purcell the Nobel Prize for Physics for 1952, 911 ; work of, 911
Bloch, H., and others : Purification of a Lipid Material ('Cord Factor') obtained from Young Cultures of Tubercle Bacilli, 124
Bloomfield, C. : Translocation of Iron in Podzol Formation, 540
Blower, Gordon : Epidermal Glands in Centipedes, 166
Blum, E. J., and others : Radio Observations of the Solar Eclipses of September 1, 1951, and February 25, 1952, 191
Blum, Harold F. : Time's Arrow and Evolution, *review* by N. W. Pirie, 992
Blundell, P. H. : Applications of Communication Theory, 1051
Blundell Rules, Ltd. : Handbook of Slide Rules, 103
Boag, J. W. : Radiation Chemistry, 196
Bode, Dr. F., and Hubener, H. J. : Identification of Uric Acid and Ascorbic Acid by Chromatography, 501
Bodenheimer, Prof. F. S. : Entomology and Citrus Fruit Production, *review* by Prof. H. C. Efflatoun, 218
  Desert Research, 301
  Biology and Productivity of Hot and Cold Deserts, 952
Boggust, Dr. W. A. (Fearon, Prof. W. R., and) : Isolation of a Carbamido Acid from Autolysed Yeast, 372
Bogorad, Lawrence, and Granick, S. : Precursors of Protoporphyrin in *Chlorella*, 321
Bohm, Dr. D. : New Research Techniques in Physics, 701
Bohr, Prof. Niels : Honorary degree of LL.D. of the University of Aberdeen conferred on, 58
Bohrer, John J., and others : Copolymerization, *review* by Prof. H. W. Melville, 1089
Boman, Hans G. : 'Double Fronting' in Paper Chromatography of Proteins, 703
Bombay Natural History Society : Fiftieth Volume of the *Journal* of the, 955
Bond, Dr. G. : Mineral Nutrition of Plants, *review*, 176
Bondi, Dr. A., and Birk, Mrs. Yehudith : A Difference in *in vitro* Pancreatic Digestion between Animal and Plant Protein Feeds, 673
Bondi, H. : Cosmology, *review* by Prof. W. H. McCrea, 768
Bondi, H., and Gold, T. : Relativity and Indeterminacy, 582
Bonet-Maury, Prof. P. : Radiation Chemistry, 195
Bonne, Prof. A. : Desert Research, 302
Bonner, John Tyler : Morphogenesis, an Essay on Development, *review* by Prof. C. W. Wardlaw, 943
Bonser, Dr. W., and Russell, Margaret P. : Cost of German Medical and Scientific Periodicals, 446

Booth, Dr. Andrew D. : Computing Machine Terminology, 986
Born, Prof. Max : Tributes in honour of his seventieth birthday (Prof M. von Laue and Prof. R. W. Pohl), 953
Bose, Monisha : Mechanism of the Reaction between Dichromate and Diphenylcarbazide, 213
Bose, Prof. S R. Identity of *Polystictus* (= *Polyporus* = *Trametes*) *cinnabarinus* (Jacq.) Fr. with *Polystictus sanguineus* (L) Fr., 1020
Boswell, Miss K. C. : *Obituary* by Miss F. C. Miller, 825
Boswell, Prof. P. G. H. : Natural Moisture-content, Porosity and Compaction of Clayey Deposits, 156
Botanical Society of Bengal . Annual General Meeting and election of Officers, 60
Botanists (Japanese) : An Address Book of (Science Council of Japan), 694
Botterill, J. R. : Awarded a Clayton Fellowship of the Institution of Mechanical Engineers, 229
Botts, J. (Morales, M., and) : Physical Chemistry of Proteins, 519
Boult, E., and others : Nature of the Solution obtained by Pyridine Extraction of Coal, 317
Bourne, Dr. Geoffrey H. : Freezing and Drying, *review*, 723
  Unusual Foods for Human Consumption, 1050
Bowden, B. N. : Awarded a Nature Conservancy Research Fellowship in Botany, 524
Bowen, Dr. E J. : Luminescence of Solids, *review*, 259
  Fluorescence of Organic Compounds, *review*, 296
Bowen, Dr. E. J., and Rohatgi, Miss K. K. : Reactivity of Free Radicals, 820
Bowen, Jun., W. A., and others : Dynamo Currents and Conductivities in the Earth's Upper Atmosphere, 1093
Bowen (Cables and Plastics) Prize Fund . Awards for 1953 (British Plastics Federation), 564
Boyd, Dr. R. L. F. Electrical Discharges in Gases, 602, 603
Boyd–Orr, Rt. Hon. Lord *Obituary* of Sir Jack Drummond, 402
Boyko, Dr. Hugo : Biology and Productivity of Hot and Cold Deserts, 951
Braams, C M. : The Symmetrical Spherical Top, 31
Braarud, Prof. T., and Nordli, E. . Coccoliths of *Coccolithus huxleyi* seen in an Electron Microscope, 361
Bracewell, Dr. R. N. : Awarded a Radio Section Premium of the Institution of Electrical Engineers, 19
Bradbury, E. : The Effect of the Temperature of Preparation on the Mechanical Properties and Structure of Gelatine Films, 24
Braden, A W. H. (Austin, C R., and) Passage of the Sperm and the Penetration of the Egg in Mammals, 919
Bradfield, Dr. A E., and others : Chlorogenic Acids in Fruit Trees, 168
Bradfield, G. Promoted a Senior Principal Scientific Officer in the Scientific Civil Service, 309
  Measurement and Importance of Elastic Properties of Metals, 527
Bradley, Prof. James Chester Elected president of the International Commission on Zoological Nomenclature, 1003
Bradley, Kenneth : Appointed director of the Imperial Institute, 912 ; work of, 912
Bradshaw, Dr. Eric Appointed to the chair of electrical engineering in the University of Manchester, 185 ; work of, 185
Bragg, Sir Lawrence The Structure of Proteins, 54
Brain, Sir Russell . The Contribution of Medicine to our Idea of the Mind, 58
Braine, Bernard : Colonial Research and Development, 871
Brandt, the late C. W., and Thomas, B. R. : Chemical Differentiation of the Genera *Podocarpus* and *Dacrydium*, 1018
Branion, Dr. H. D , and others Sir Jack Drummond, F R.S., 1131
Braude, Dr. E A. R. : Appointed to the University of London readership in organic chemistry at the Imperial College of Science and Technology, 829
Braun, Dr. P. B. : Crystal Structure of $BaFe_{12}O_{19}$, 708
  A Superstructure in Spinels, 1123
Brauns, Friedrich Emil : The Chemistry of Lignin, *review* by Dr. Julius Grant, 338
Brazier, Dr. L. G Insulation of Electrical Equipment, 1006
Brazilian Academy of Sciences, and others : Symposium on New Research Techniques in Physics, 19, 700
Brech, E. F. L. A Philosophy of Management, *review*, 430
Bremner, P. C. (Thomson, Andrew, and) Permafrost Drilling and Soil-Temperature Measurements at Resolute, Cornwallis Island, Canada, 705
Brett, H. W. W. : Awarded a Postgraduate Research Scholarship by Courtauld's Scientific and Educational Trust Fund, 346
Brett, Olive E. : Basic Chromosome Numbers in the Genus *Cerastium*, 251
Brewin, D. R. : Appointed agricultural officer, Tanganyika, 608
Brewing Industry Research Foundation, Nutfield, 830
Briggs, Prof. G. E : The University Training of a Botanist, 773
Brightman, R. Control of Public Expenditure in Britain, *review*, 337
  Science and Society, *review*, 468
  A Philosophy for Modern Man, *review*, 1085
Brindley, G W (edited by) X-Ray Identification and Crystal Structures of Clay Minerals, *review* by Dr. F. A. Bannister, 337
Bristol City Museum : Annual Report for 1951, 913
Bristowe, Dr. W. S Unusual Foods for Human Consumption, 1050
British Agricultural History Society : Inaugural meeting of the, 440
British Association for the Advancement of Science Presidential Address (Prof. A. V. Hill), 388
  Summaries of Addresses of Presidents of Sections, 393
  Presidential Address to Section A, Mathematics and Physics (Prof. A. M. Tyndall), 393
  Presidential Address to Section B, Chemistry (Prof. W. Wardlaw), 394
  Presidential Address to Section C, Geology (Dr. J E. Richey), 394
  Presidential Address to Section D, Zoology (Prof. A. D. Peacock), 395
  Presidential Address to Section E, Geography (Prof. R. O. Buchanan), 395
  Presidential Address to Section F, Economics (Prof. D. T. Jack), 396
  Presidential Address to Section G, Engineering (Sir Ben Lockspeiser), 396
  Presidential Address to Section H, Anthropology and Archæology (Prof. E. O. James), 397
  Presidential Address to Section I, Physiology (Prof. R. C. Garry), 398
  Presidential Address to Section J, Psychology (Prof. P E. Vernon), 398
  Presidential Address to Section K, Botany (Prof. Meirion Thomas), 399
  Presidential Address to Section L, Education (A. L Binns), 399
  Presidential Address to Section M, Agriculture (Dr. N. C. Wright), 400
  Presidential Address to the Conference of Delegates of Corresponding Societies (J. A S. Standall), 401
  Election of Sir Edward Appleton as president for 1953, 440
  Symposium on Some Factors affecting Choice and Judgment, 555
British Association for the Advancement of Science, Section A (Mathematics and Physics) : Discussion on Electrical Discharges in Gases, 601
  Discussion on Moisture Relations and Textile Fibres, 732
British Association for the Advancement of Science, Section B (Chemistry) Discussion on Chemistry and Food Processing, 603
  Discussion on Biologically Significant Macromolecules, 690
  Discussion on Fibres, Old and New, 865
British Association for the Advancement of Science, Section D (Zoology) : Discussion on the Behaviour of Ants, Bees and Termites, 642
  Discussion on Recent Advances in Cytology, 655
British Association for the Advancement of Science, Sections D (Zoology) and I (Physiology) : Discussion on the Comparative Physiology of Muscles, 996
British Association for the Advancement of Science, Sections D (Zoology), I (Physiology), J (Psychology), and K (Botany) : Discussion on Human Biochemical Genetics, 654
British Association for the Advancement of Science, Section G (Engineering) : Discussion on Education and Training in Chemical Engineering, 644
British Association for the Advancement of Science, Section H (Anthropology and Archæology) : Discussion on Technical Aids in Archæology, 909
British Association for the Advancement of Science, Section I (Physiology) : Discussion on Energy into Nerve Impulses, 823
British Association for the Advancement of Science, Sections I (Physiology) and M (Agriculture) : Discussion on Antibiotics in Animal Nutrition, 868
British Association for the Advancement of Science, Section J (Psychology) Discussion on Resistance to Change, 688
British Association for the Advancement of Science, Sections J (Psychology) and M (Agriculture) : Symposium on Resistance to Change in Farming, 688
British Association for the Advancement of Science, Section K (Botany) : Discussion on the Botany of Flax, 557
  Discussion on the University Training of a Botanist, 770
British Association for the Advancement of Science, Section K* (Forestry) : Discussion on Afforestation of Moorland, 734
British Association for the Advancement of Science, Section L (Education) : Discussion on the Education of the Deaf, 525
British Association for the Advancement of Science, Section M (Agriculture) : Discussion on Problems of the Small Farm, 740
British Cast Iron Research Association (Dr. J. G. Pearce), 153
British Coal Utilization Research Association : Coal Science Lecture (Sir Alfred Egerton), 93
  Annual Report for 1951, 237
British Cotton Industry Research Association : Shirley Institute Year Book 1951, 144
British Empire Cancer Campaign A Survey of Cancer in London (Dr W. L. Harnett), *review* by Dr. I. Doniach, 220
  Twenty-ninth Report, 1951 (edited by Sir Heneage Ogilvie), 515
British Gelatine and Glue Research Association : Fifth Research Panel Meeting, 24
British Glues and Chemicals, Ltd. : Demonstration of the Chayen Process for Extraction of Oils and Fats, 881
British Industries, Federation of (Industrial Research Committee) : Research and Development in the British Industry, a Survey of Expenditure on Industrial Research and Development in the Year 1950–51, 465
British Institution of Radio Engineers : Awards for 1951, 308
  Nomination of William E. Miller as president-elect, 308
British Internal Combustion Engine Research Association : Election of Officers, 347
British Interplanetary Society : Annual Report for 1951, 346
  The Artificial Satellite (edited by L. J. Carter), 486
British Iron and Steel Research Association (Constitution of Alloys Group) . Research on the Constitution of Alloys, 305
British Library of Political and Economic Science . Annual Report for 1950–51, 188
British Memorial Fund in Victoria Fellowships in Natural Science, Industrial Research, Virology and Agriculture, 189
British Museum (Natural History) : Promotion of W. N. Edwards to the rank of deputy chief scientific officer, 782
  Appointment of Dr. F. A. Bannister as keeper of the Department of Mineralogy, 782, 1000
  Appointment of A. C. Townsend as deputy keeper in charge of the Library, 782
  Retirement of Dr. W. Campbell Smith as keeper of the Department of Mineralogy, 1000
British Mycological Society—Plant Pathology Field Day (R. V. Tipler), 409
British Ornithologists' Union and the British Trust for Ornithology : Ornithological Conference at Bamburgh, 227
British Pharmacological Society and the Fine Chemicals Group of the Society of Chemical Industry : Symposium on Anticholinesterases, 1100
British Plastics Federation Awards from the Bowen (Cables and Plastics) Prize Fund, 564
British School of Archæology at Athens : Annual Report for the Session 1950–51, 269
British Scientific Instrument Research Association : Open Days at the laboratories at Chislehurst, 739, 1007
  Bulletin, 1001
British Social Biology Council . Conference on Race Problems, 784
British Society of Rheology Symposium on Emulsions and Films, 232
  Election of Officers, 653
  Conference on Plasticity of Materials, 875
British Standards Institution New Appointments, 226
British Thomson-Houston Co , Ltd . Engineering Research Fellowships, 59
  Research Developments by, 483

British Trust for Ornithology (British Ornithologists' Union and the): Ornithological Conference at Bamburgh, 227
British Welding Research Association: New Fatigue Testing Laboratory at Abington, Cambridge (A. A. Wells), 109
Broad, Prof. C. D.: Ethics and the History of Philosophy, *review* by Prof. A. D. Ritchie, 992

NAME INDEX

Cassidy, Prof. H. G. : Principles and Applications of Ion Exchange, 152
Cassie, Dr A. B. D : Moisture Relations of Textile Fibres, 733, 734
Cast Iron Research Association, British (Dr. J. G. Pearce), 153
Castro, Josué de : Geography of Hunger, *review* by Mrs. M. W. Grant, 259
Cates, Dr. J. E. : The Posterior Pituitary Gland, 198
Catton, W. T. (Burtt, E. T., and) : Nerve Impulses originating from the Compound Eye of the Locust, 285
Caullery, Maurice : Parasitism and Symbiosis, translated by Dr. Averil M. Lysaght, *review* by Dr. G. Lapage, 91
Cavallero, Prof. C., and others Effect of Cortisone on the Blood Pressure of Normal Rats, 43
Cawley, A. : Appointed director, Geological Survey, Uganda, 269
Ceccarelli, M., and others : Observation of a τ-Meson, 454
Cement and Concrete Association (Building Research Station of the Department of Scientific and Industrial Research and the) : International Symposium on the Chemistry of Cement, 347, 785
Centre National de la Recherche Scientifique : Colloques Internationaux, 10, Réactions dans l'état solide, Paris, Octobre 1948 ; 30, Réarrangements moléculaires et Inversion de Walden, Montpellier, Avril 1950 ; *review* by Prof. J. R. Partington, 944
Chadwick, C. S. : Awarded a Postgraduate Research Scholarship by Courtauld's Scientific and Educational Trust Fund, 346
Chain, Dr. E. B. : Elected a foreign correspondent of the Paris Academy of Sciences, 61
Challen, S. B. : The British Pharmaceutical Conference 1952, 787
Challice, C. F. : Spermatozoan Morphology, 232
Chalmers, Barbara (Burges, Prof. Alan, and) : *Neurospora* following a Volcanic Eruption, 459
Chalonge, M. D. Twenty Years of Work at the Jungfraujoch, 186
Chamberlain, G. H. N., and others : Reactivity of Free Radicals, 820
Chambers, S. B. : Appointed government statistician, Nigeria, 1003
Champion, Prof. H. G. : Text-Book of Silvicultural Systems, *review*, 816
Channugam, J., and Ashmore, Dr. P. G. : The Hydrogen-Oxygen Reaction Sensitized by Nitrosyl Chloride, 1067
Channon, J. A. : Appointed meteorologist, East Africa High Commission, 1003
Chapiro, A. : Radiation Chemistry, 195
Chaucer's Astronomy (Dr. Derek J. Price), 474
Chayen, J. : Pectinase Technique for Isolating Plant Cells, 1070
Chelsea Polytechnic, London : Retirement of Dr. B. Barnes as head of the Department of Biology, 870
Appointment of C. C. Hentschel as head of the Department of Biology, 870
Appointment of Dr. Mary F. Lockett as head of the Department of Physiology, 870
Chemical Industry, Society of : Messel Memorial Lecture (Sir Henry Tizard), 427
Chemical Industry, Society of (American Section) : Perkin Medal for 1953 awarded to Dr. Charles Allen Thomas, 954
Chemical Industry, Society of (Fine Chemicals Group) (British Pharmacological Society and the) : Symposium on Anticholinesterases, 1100
Chemical Industry, Society of (Nutrition Panel of the Food Group) : Symposium on Food and the Future, 956
Chemical Industry, Society of, and others : Symposium on the Principles and Applications of Ion Exchange, 150
Chemical Laboratory of India, National : Appointment of Prof. G. I. Finch as director, 225
Chemical Research Laboratory, Teddington Open Days, 103, 648
Report for 1951, 1109
Chemical Society (Research Fund) Grants for research in chemistry, 145
Chemical Society, and others : Symposium on the Principles and Applications of Ion Exchange, 150
Chemical Society of the University of Edinburgh, 101
Chemistry, Royal Institute of, and others Symposium on the Principles and Applications of Ion Exchange, 150
Chemistry, Royal Institute of (London and South-Eastern Counties Section), and others : Discussion on the Place of the Scientist in Civil Defence, 406, 957
Chemistry (Analytical), Midlands Society for : Symposium on Analytical Chemistry, 307
Chemistry (Pure and Applied), International Union of : Meetings of the Analytical Chemistry Section, 60
First International Congress on Analytical Chemistry, 60, 599
Cherry, E. C. : Degree of D.Sc.(Eng.) of the University of London awarded to, 19
Applications of Communication Theory, 1052
Cherwell, Lord : New Physics and Engineering Laboratories at King's College, London, opened by, 261
Associateship of the Manchester College of Technology conferred on, 651
Chicago Museum of Science and Industry : Exhibition of Geometry arranged by the Illinois Institute of Technology, 103
Chimie Solvay, Institut International de : Huitième Conseil de Chimie tenu à l'Université de Bruxelles, Septembre 1950—Le mécanisme de l'oxydation, Rapports et discussions, *review* by Prof. J. R. Partington, 944
Chinnayya, E. J : Colonization of Plant Debris by *Coprinus* Species in Soils, 252
Chisholm, Dr. J. S. R The S-Matrix, 515
Chitale, R. P., and others : Biosynthesis of Vitamin C and a New Precursor, 545
Chossudovsky, Dr. E. M. : Housing in the U.S.S.R., 351
Christensen, Prof. Clyde M. : The Molds and Man, *review* by Dr. J. Grainger, 1088
Christensen, G. N. (Barkas, Dr. W. W., and) : Plasticity of Materials, 876
Christie, S. M. H., and others : Total Synthesis of Flavin-adenine-dinucleotide, 924
Christophers, Sir Rickard : Awarded the Buchanan Medal of the Royal Society, 826, 948 ; work of, 948
Christy, Dr. R. F. : Medium-Energy Nuclear Physics, 349
Chubb, Dr. Basil : The Control of Public Expenditure—Financial Committees of the House of Commons, 171, *review* by R. Brightman, 337
Chun Yu Lin, Robert : Pharmacological and Toxicological Actions of Dart Poison used in Malaya, 416
Churchill-Davidson, H. C., and Richardson, A. T. : Motor End-Plate Differences as a Determining Factor in the Mode of Action of Neuro-Muscular Blocking Substances, 617
Chute, Dr. L., and others : Sir Jack Drummond, F.R.S., 1131
City and Guilds College, London : Course of lectures on Nuclear Reactors, 308
City and Guilds of London Institute : Conferment of Fellowships, 406
Exhibition entitled Training for Industry, 739
Establishment of an Insignia Award, 828
Civil Defence : Regional Scientific Advisers for (Home Office appointments), 737
Civil Engineers, Institution of : Awards for 1951–52, 870
Ewing Gold Medal awarded to Prof. J. F. Baker, 1100
Civil Service, Scientific : Promotion of Individual Research Workers, 309
Appointment of Dr. T. H. C. Taylor as deputy director (Senior Principal Scientific Officer grade) at the Anti-Locust Research Centre, London, 1049
Clapham, Prof. A. R. : The University Training of a Botanist, 773
Clark, Colin G. : Appointed director of the Institute for Research in Agricultural Economics at Oxford, 189
Clark, D. : Awarded a Ramsay Memorial Fellowship in Chemistry, 60
Clark, Prof. George L., and others : A Basic Course in the Theory and Practice of Quantitative Chemical Analysis, *review*, 727
Clark, Margaret M. Measurement and Interpretation of Eye-Dominance, 192
Clark, N. : Awarded a Textile Institute Scholarship, 956
Class, P. : Appointed an agricultural officer, Federation of Malaya, 61
Clausen, Jens Stages in the Evolution of Plant Species, *review* by Dr W. B. Turrill, 385
Clay, Dr. S. : Colour, *review*, 859
Clay, Theresa (Rothschild, Miriam, and) : Fleas, Flukes and Cuckoos, *review* by Dr. E Hindle, 382
Clegg, John : The Freshwater Life of the British Isles, *review* by H. C. Gilson, 681
Cleland, Dr. K. W. : Permeability of Isolated Rat Heart Sarcosomes, 497
Cleland, Dr. K. W. (Slater, Dr. E. C., and) : Stabilization of Oxidative Phosphorylation in Heart-Muscle Sarcosomes, 118
Cleveland, S. D. : The Inevitability of Museums, 354
Clifford, D. S., and others : Failure of Vacuum Insulation at Low Field Strengths, 503
Clow, Dr. Archibald, and Clow, Nan L The Chemical Revolution, *review* by W. L. Sumner, 386
Cloudsley-Thompson, Dr J. L. Biology of Deserts, 951
Coal Board, National Grant of £1,500 a year for three years to the University of Oxford for research in the Department of Human Anatomy, 871
Coal Utilization Research Association, British Coal Science Lecture (Sir Alfred Egerton), 93
Annual Report for 1951, 237
Coates, Dr. M. E. : Antibiotics in Animal Nutrition, 868
Coates, Wells : Freedom and Responsibility, 217
Cockburn, A. M. : Appointed agricultural officer, Nigeria, 1003
Cocks, M. : Surface Oxide Films in Intermetallic Contacts, 203
Cohen, Prof. I. B. Lightning Protection, 1099
Cohen, Dr. John : Temporal Integration as a Clue to Mind, *review*, 297
Appointed to the chair of psychology at the University of Manchester, 440 ; work of, 440
Mental Epidemiology, *review*, 472
Clinic and Society, *review*, 592
The World of Touch, *review*, 815
Cohen, Dr. S. S. (Wyatt, Dr. G. R., and) Nucleic Acids of Rickettsiae, 846
A New Pyrimidine Base from Bacteriophage Nucleic Acids, 1072
Cohn, E. J. : Physical Chemistry of Proteins, 519
Cohn-Vossen, S. (Hilbert, D., and) : Geometry and the Imagination, translated by P. Nemenyi, *review*, 1089

  Leon Gaster Memorial Premium awarded to J. S. McCulloch, 651
  Honorary membership awarded to Prof. J. T. MacGregor-Morris, 651
Imperial College of Science and Technology, London: Retirement of Sir David Brunt from the chair of meteorology in the University of London and the post of head of the Department of Meteorology, 15
  Appointment of P. A. Sheppard to the chair of meteorology, 15
  Farewell Dinner in honour of Sir George Thomson, 17
  Report for the Year 1950–51, 102
  Title of professor emeritus of meteorology in the University of London conferred on Sir David Brunt, 228
  Title of professor emeritus of chemical technology in the University of London conferred on Sir Alfred Egerton, 228
  Title of professor emeritus of physical chemistry in the University of London conferred on Prof. G. I. Finch, 228
  Title of professor emeritus of mining in the University of London conferred on Prof. J. A. S. Ritson, 228
  Title of professor emeritus of physics in the University of London conferred on Sir George Thomson, 228
  Title of reader in structural geology in the University of London conferred on Dr. Gilbert Wilson, 229
  Appointment of Dr. E. A. R. Braude to the University of London readership in organic chemistry, 829

- Appointment of M. W. Humphrey Davies to the University of London readership in electrical engineering, 829
- Title of reader in mechanical engineering in the University of London conferred on Dr. William Davies, 956
- Appointment of Prof. P. M. S. Blackett to the University of London chair of physics, 1003
- Title of reader in organic chemistry in the University of London conferred on Dr. L. N. Owen, 1003
- Vacation School on the Insulation of Electrical Equipment, 1006, 1100

- Imperial College of Tropical Agriculture, Trinidad : Resignation of Harold James Page as principal, 564
- Imperial College of Tropical Agriculture, Trinidad, and the Government of Colombia : Cacao Collecting Expedition to Colombia, 441
- Imperial Institute, London : Report of the Committee of Inquiry into the (Ministry of Education), 899
  - Retirement of Sir Harry Lindsay as director, 912
  - Appointment of Kenneth Bradley as director, 912
  - Questions in the House of Lords on its transfer, 1048
- Indian Association for the Cultivation of Science : Annual Report for 1951–52, 881
- Indian Jute Mills Association : Formal opening of the new buildings of the Research Institute, 18
- Indian Sociological Society : Publication of the *Sociological Bulletin*, 481
- Inglis, Dr. D. R. : Medium-Energy Nuclear Physics, 349
- Ingold, Prof. C. K. : Awarded a Royal Medal of the Royal Society, 870, 946 ; work of, 946
- Ingold, Prof. C. T. : The University Training of a Botanist, 774
- Ingold, K. U., and others : Reactivity of Free Radicals, 819
- Ingram, J. M. A., and others : β-Oxidation of ω-Phenoxyalkylcarboxylic Acids in the Flax Plant, 887
- Ingram, Dr. M. : Aspects of Food Preservation, 444
- Ingram, Vernon M. : Isoelectric Point of Chymotrypsinogen by a Donnan Equilibrium Method, 250
- Insectes Sociaux, Union Internationale pour l'Étude des : Request to the Royal Entomological Society of London to form a British Section, 61
- Institut International de Chimie Solvay : Huitième Conseil de Chimie tenu à l'Université de Bruxelles, Septembre 1950—Le mécanisme de l'oxydation, Rapports et discussions, *review* by Prof. J. R. Partington, 944
- Inter-African Labour Institute : Appointment of Miss Sheila Ann Ogilvie as director, 523
- Internal Combustion Engine Research Association, British : Election of Officers, 347
- International Association for Bridge and Structural Engineering : Fourth Congress of the, 485
- International Astronautical Federation : Election of Officers, 1053
- International Astronomical Union : Eighth General Assembly, 60, 229, 785
  - Symposium on Stellar Evolution, 786
  - Symposium on the Astrometry of Faint Stars, 786
  - Symposium on Instruments, 786
- International Commission on Acoustics : International Congress on Electro-acoustics, 1100
- International Commission on Glass : Annual Meetings, 101
- International Commission on Zoological Nomenclature : Election of Prof. J. C. Bradley as president, 1003
- International Committee for Bird Preservation (European Continental Section) : Fifth Conference, 97
- International Council for the Exploration of the Sea (R. S. Wimpenny), 906
  - Jubilee Celebrations, 523
- International Council of Scientific Unions : General Assembly in Amsterdam, 60, 960
  - Abstracting Board of the, 954
- International Federation for Documentation : Conference in Copenhagen, 1103
- International Fertility Association, 564
- International Geographical Union : Eighth General Assembly, 60
- International Health Organizations (Sir Arthur MacNalty), 108
- International Institute of Welding : Annual Meeting in Gothenburg, 307
- International Scientific Film Association : Sixth Congress of the, 406
  - Sixth Annual Congress (J. Stewart Cook), 1005
- International Union of Biological Sciences : Meeting of the Executive Committee, 23
- International Union of Biological Sciences (Zoological Section) : Preparation of an Index of Zoologists, 189
- International Union of Pure and Applied Chemistry : Meetings of the Analytical Chemistry Section, 60
  - First International Congress on Analytical Chemistry, 599
- International Union of Theoretical and Applied Mechanics : Third General Assembly, 60
- International Union of Nutritional Sciences : Symposium on Present Problems in Nutritional Research, 442
- International Union of Pure and Applied Physics (International Commission on Acoustics) : International Congress on Electroacoustics, 1100
- International Union of Pure and Applied Physics, and others : Conference on Beta- and Gamma-ray Radioactivity, 229
- International Scientific Radio Union : Tenth General Assembly, 60, 152

Larose, Dr. P. (Fischer, R, and): Factors Governing the Adaptation of Bacteria against Quaternaries, 715
Laue, Prof. M. von To present the Max Planck Medal for 1952 to Prof. P. A. M. Dirac on behalf of the Association of German Physics Institutes, 695
Laue, Prof. M von, and Pohl, Prof R W. Tributes in honour of the seventieth birthday of Prof. Max Born, 953
Laurent, Prof. T. Applications of Communication Theory, 1052
Lauritsen, Dr. C. C Some Investigations of Light Nuclei, 612
Lauritsen, Dr. T.. Medium-Energy Nuclear Physics, 350
Lauterbach, Theodore M The Origin and Development of the Allegheny Observatory of the University of Pittsburg, 1008
Laver, F. J. M.: Awarded a Radio Section Premium of the Institution of Electrical Engineers, 19
Lawday, Dorothy Detection of Digitalis Glycosides on Paper Chromatograms, 415
Lawden, D. F. Awarded a Measurements Section Premium (Mather Premium) of the Institution of Electrical Engineers, 19
  Interorbital Transfer with Minimum Propellant Expenditure, 1053
Lawn, Prof. J G.: *Death* of, 781; *obituary* by Prof. J A S Ritson, 1046
Lawrence, Dr. A. S C: Emulsions and Films, 232
Lawrence, J. J. · Toxicity of Methylene Blue to *Leptospira icterohaemorrhagiae*, 327
Lawrence, W. Applications of Communication Theory, 1052
Lawrie, R. A.: Biochemical Differences between Red and White Muscle, 122
LeFèvre, Prof. R. J. W Awarded the H. G. Smith Memorial Medal by the Royal Australian Chemical Institute, 1049
LeRoy, D. J (Berlie, M R., and) · Reactivity of Free Radicals, 819
LeRoy, D. J (Wetmore, F. E. W., and) · Principles of Phase Equilibria, *review* by Prof. J R Partington, 859
Lea, A. J. · Solubility of Melanins, 709
Lea, Prof. F. C. *Death* of, 605; *obituary*, 781
Lea, Dr. F. M. · The Chemistry of Cement, 786
Leach, E W Appointed director of agriculture, Gold Coast, 60
Leather Trades' Chemists, Society of · Annual Conference, 1054
  Fifth Procter Memorial Lecture (Prof. J. B Speakman), 1054
Leathercraft, Museum of · Establishment of a, 606
Leathley, J. A. Awarded a Postgraduate Research Scholarship by Courtauld's Scientific and Educational Trust Fund, 346
Lee, A. J, and others. Recent Echo Sounder Studies, 71
Lee, H. John (Marston, Hedley R, and) Cobalt in the Nutrition of Ruminants—Response of Cobalt-deficient Sheep to Massive Doses of Vitamin B_{12}, 791
Lee, H. W · The Glass-Polisher's Art, *review*, 553
Lee, M. R., and others · Internal Fissuring of Wheat due to Weathering, 533
Lees, Prof. C. H. · *Death* of, 561, *obituary* by Dr. Ezer Griffiths, 650
Leeson, Colonel H. B Electricity and Current Affairs, 874
Leeuw, A. de. Desert Research, 302
Lefort, Dr. M.: Radiation Chemistry, 196
Legendre, R.. Edmond About and the Technique of Freezing and Drying Tissues, 1080
Leicester, Henry M. (editor-in-chief): Chymia, Annual Studies in the History of Chemistry, Vol. 3, *review*, 596
Leicester Museum and Art Gallery Publication of a *Bulletin*, 607
Leigh, Dr. R S. Measurement and Importance of Elastic Properties of Metals, 529
Leighly, Prof F. B. · Desert Research, 301
Lennard-Jones, Sir John · Appointed principal of the University College of North Staffordshire, 912; work of, 912
Leonard, C. D. (Stewart, Dr Ivan, and). Molybdenum Deficiency in Florida Citrus, 714
Leonardo da Vinci, Artist and Man of Science (1452–1519), (Dr. A Tindell Hopwood), 135
Leone, Dr. G. · Desert Research, 301
Leopoldina Academy, Schweinfurt Tercentenary of the (Dr. R C H Young), 1105
Leston, D. Appointed editor of *The Entomologist*, 695
Leverenz, Humboldt W An Introduction to Luminescence of Solids, *review* by Dr. E J. Bowen, 259
Levin, B, and Oberholzer, V. G. Paper Electrophoresis of Serum Proteins, 123
Levvy, Dr. G. A, and others: Glucuronide Decomposition in the Digestive Tract, 163
Lewin, L: Awarded a Radio Section Premium of the Institution of Electrical Engineers, 19
Lewis, Dr A G. · The Posterior Pituitary Gland, 198
Lewis, Prof. A. J. · Appointed a member of the Medical Research Council, 524
Lewis, Dan. Degree of D.Sc. of the University of London conferred on, 956
Lewis, Prof. H. D.. Freedom and Responsibility, 217
Lewis, J.: Newspaper Libraries, 563
Lewis, Roy Moving a Factory, 268
Lewis, R. P. Waldo, and McIntosh, D H Geophysical and Meteorological Changes in the Period January–April 1949, 488
Lhotka, Dr. John F.. Histochemical Differentiation of *cis-trans* 1-2 Glycols, 751
Library Association: Pamphlet No. 11, Newspaper Libraries (J. Lewis), 563
  Pamphlet No. 4, The Development and Administration of a Special Library (C H. Tomalin), 956
Liddiard, E. A. G.. *Obituary* of Colonel W. C Devereux, 141
Lide, David R. Awarded a Ramsay Memorial Fellowship in Chemistry, 60
Lin, Robert Chun Yu: Pharmacological and Toxicological Actions of Dart Poison used in Malaya, 416
Lindblad, Prof. B. · Elected president of the International Council of Scientific Unions, 960
Lindblad, Prof. Bertil, and Elvius, Aina: A Diffraction Corona near the Centre of the Spiral Nebula NGC 4216, *erratum*, 61
Lindegren, Prof. Carl C, and Lindegren, Gertrude: Proximity of Genes controlling the Fermentation of similar Carbohydrates in Saccharomyces, 965
Lindquist, Wold Cell Surface Constituents and Yeast Flocculation, 544
Lindsay, Sir Harry Retirement as director of the Imperial Institute, 912; work of, 912
Line, R, and others: Reclaiming Land for Agriculture, *review* by G V. Jacks, 858
Linnaeus, Carl (Knut Hagberg), translated from the Swedish by Alan Blair, *review* by Prof. F. J. Cole, 1036
Linnean Society of London: Discussion on Classification of the Fungi, 997
Linsdale, Jean M, and Tevis, Jr., Lloyd P. The Dusky-footed Wood Rat, *review* by Dr L. Harrison Matthews, 471
Linser, H.: Prospecting by Geophysical Methods, 230
Linstead, Prof. R P. Frontiers of Organic Chemistry, *review*, 993
Lipinski, J.: Awarded a Radio Section Premium of the Institution of Electrical Engineers, 19
Lipschutz, Dr. A.. Steroid Hormones and Tumors, *review* by Dr. A S Parkes, 178
Lipschutz, Dr A., and others Structural Features of Antitumorigenic Corticoids, 917
List, Robert J (prepared by) · Smithsonian Meteorological Tables, sixth revised edition, *review* by G. A. Bull, 175
Lister, Dr. B. A. J.. Principles and Applications of Ion Exchange, 151
Lister, N. W. (Nash, K. L, and): Streaming Potential and Electro-osmosis—Mechanism of Electro-osmosis, 837
Lister Institute of Preventive Medicine. Retirement of Sir Alan Drury as director, 19, 57
  Appointment of Dr. A. A. Miles as director, 19, 57
Little, Dr. K.. Irradiation of Linear High Polymers, 1075
Little, Dr. K., and Kramer, H.: Nature of Reticulin, 499
Littlewood, H K. · Appointed principal veterinary officer, Western Region, Nigeria, 61
Livingston Prof Robert, and Weil, Sanford Activation of the Fluorescence of Chlorophyll Solutions, 750
Livingston, Dr. Robert S.: The Oak Ridge 86-inch Cyclotron, 221
Llewelyn, D. A. B · Appointed scientific officer, East Africa High Commission, 564
Lloyd, R G.: The Law of Patents, *review*, 49
Lochhead, A. G., and others · A Bacterial Growth-factor Synthesized by a Soil Bacterium, 282
Lockett, Dr. Mary F.. Appointed head of the Department of Physiology at Chelsea Polytechnic, 870, work of, 870
Lockhead, A G (Burton, M O., and) Synthesis of Vitamin B_{12} by *Rhizobium meliloti*, 913

Lockley, R. M. : The Fulmar Population, *review*, 725
  British Amateur Ornithologist's Vade-Mecum, *review*, 944
Lockspeiser, Sir Ben : Desert Research, 302
  Progress in Aeronautical Science and Engineering, 396
  Education and Training in Chemical Engineering, 644
  The Chemistry of Cement, 785
  To open the Humber Laboratory at Hull of the Torry Research Station, 829
Loeb, Dr. J. · Applications of Communication Theory, 1052
Loeb, Prof R F. . Degree of doctor *honoris causa* of the University of Paris conferred on, 1048
Loewenthal, Dr. H. J. E · Awarded an Imperial Chemical Industries Fellowship at the University of Glasgow, 913
Lofgren, B., and others . Toxicity of Dextran in Rats, 125
Logan, W. E. M. : Appointed regional assistant conservator of forests, Tanganyika, 1003
London Hospital Medical College : Appointment of Dr. F. L Warren to the University of London chair of biochemistry, 60
  Title of professor emeritus in bacteriology in the University of London conferred on Prof. S. P. Bedson, 228
  Title of professor emeritus of chemical pathology in the University of London conferred on Prof J. R. Marrack, 228
London School of Hygiene and Tropical Medicine : Retirement of Prof. H. E Shortt from the University of London chair of medical protozoology, 100
  Appointment of Dr P. C. C. Garnham to the University of London chair of medical protozoology, 100
London and Home Counties Regional Advisory Council . Report on the Training of Designers for the Printing Industry, 18
Long Ashton Research Station: Open Day (R. W. Marsh), 263
Long Range Weapons Establishment, Australia . Appointment of Dr. C F. Bareford as chief superintendent, 1047
Longe, J. O. I. . Appointed an agricultural officer, Nigeria, 60
Lopes, Prof. J. Leite New Research Techniques in Physics, 701
Lord, Dr. Mary P. : Eye Rotations with Change of Accommodation, 670
Lossing, F. P., and others Reactivity of Free Radicals, 819
Loudon, Dr J. D. . Appointed a senior lecturer in chemistry at the University of Glasgow, 19
Lovell, A. C B., and others Velocity Distribution of Sporadic Meteors, 872
Lovern, Dr. J. A. : Chemistry and Food Processing, 604
Lovis, J. D. . Awarded a Nature Conservancy Research Studentship in Botany, 524
Low, Dr. Barbara W. The Structure of Proteins, 54
Low, Dr. Barbara W , and Richards, Frederic M. . Determination of Protein Crystal Densities, 412
Lowdermilk, Dr W. C Desert Research, 300, 301
Lowe, E. J. (Corbridge, D E C., and) Structure of White Phosphorus—Single Crystal X-Ray Examination, 629
Lowenthal, H J. E. . Appointed Imperial Chemical Industries, Ltd , research fellow in organic chemistry at the University of Glasgow, 19
Lowther, E. H. N. (Bates, Lieut.-Colonel R S. P , and) Breeding Birds of Kashmir, *review*, 511
Lowy, J. · Comparative Physiology of Muscles, 996
Lubin (David) Memorial Library of the Food and Agriculture Organization of the United Nations Inauguration of the, 59
Lundberg, Dr. A. (Job, C., and) · Excitation of Ganglion Cells in the Inferior Mesenteric Ganglion by Collaterals, 205
Lundquist, Dr Frank, and Seedorff, Dr. Hans Henrik Pepsinogen in Human Seminal Fluid, 1115
Lunnon, J. Barbara, and others Adrenal Cortical Hormones in Human Placenta, 494
Lush, Miss P A. Secondary Piliferous Layer in the Lupin, 127
Lyall, W. McC Appointed field geologist, Kenya, 1003
Lysenko's Latest Discovery—The Conversion of Wheat into Rye, Barley and Oats (Prof. P Maheshwari), 66

MABON, R M . Appointed laboratory assistant, Veterinary Department, Tanganyika, 269
MacArthur, Dr. J. · Title and status of reader in biomolecular structure in the University of Leeds conferred on, 143
McBain, Prof J W · Elected an honorary life member of the Faraday Society, 305
Macbeath, Prof. A. Experiments in Living, a Study of the Nature and Foundation of Ethics or Morals in the Light of Recent Work in Social Anthropology, *review* by Lord Raglan, 174
Macbeath, Dr. A. M. · Appointed senior lecturer in mathematics at the University College of North Staffordshire, 653
Maccabaeans, Society of Meldola Medal for 1953, 739
McCabe, Dr L. C. : Energy in the Service of Man, 611
McCallum, A. Appointed agricultural officer, Tanganyika, 269
McCarthy, Frederick D . Aboriginal Rain-Makers, 26
McClendon, Dr. John H., and Blinks, Prof. L. R. : Use of High Molecular Weight Solutes in the Study of Isolated Intracellular Structures, 577
McClung, Robert M Appointed acting curator of the Mammal and Bird Collections in the New York Zoological Park, 345
McClure, T J. Correlation Study of Bovine Erythrocyte Antigen A and Butterfat Test, 327
McColvin, Lionel R. : Library Services in the British Colonial Territories, 169
McCoy, Dr. J. H Farm Water Supplies, 1107
McCrea, Prof. W H Progress in Cosmology, *review*, 768
McCreary, Dr. J. F., and others . Sir Jack Drummond, F.R S., 1131
McCulloch, J. Appointed principal veterinary officer, Eastern Region, Nigeria, 61
McCulloch, J. S. Awarded the Leon Gaster Memorial Premium of the Illuminating Engineering Society, 651
McCusker, Prof C. B. A., and others Gaseous Contamination of Geiger–Muller Counters, 501
McDonald, D. Insulation of Electrical Equipment, 1006
McDonald, Dr. E. L. : Awarded a Rockefeller Travelling Fellowship in Medicine by the Medical Research Council, 189
Macdonald, James Forestry Nursery Technique, 736
Macdonald, J A. B · Afforestation of Moorland, 735
MacDonald, R. H. . Awarded a Telford Premium of the Institution of Civil Engineers, 870
McDowall, Ian, and Vose, W. Anomalous Properties in Quartz, 366
  Sedimentation of Halloysite, 368
Mace, Prof. C. A. : Resistance to Change, 688
McEwan, A. C., and Tipper, Dr. C. F. H. : Slow Combustion of Cyclopropane, 462
McGeown, Mary G., and Malpress, Dr F. H. . Synthesis of Deoxyribose in Animal Tissues, 575
McGill University and the Arctic Institute of North America : Fellowship and Scholarships for work on Arctic or Sub-Arctic Research, 695
McGregor, J. G. : Appointed assistant meteorologist, West African Meteorological Service, 348
MacGregor-Morris, Prof. J. T. Awarded honorary membership of the Illuminating Engineering Society, 651
Machin, K. E., and Smith, F. G. Occultation of a Radio Star by the Solar Corona, 319
Machowicz, J T. . Awarded a Radio Section Premium of the Institution of Electrical Engineers, 19
McIntosh, D H. (Lewis, R P. Waldo, and) . Geophysical and Meteorological Changes in the Period January–April 1949, 488
MacKay, Dr D. M. : Applications of Communication Theory, 1051, 1053
Mackay, G. : Honorary Fellowship of Heriot-Watt College, Edinburgh, conferred on, 142
McKay, Prof. Robert · Sugar Beet Diseases in Ireland, *review* by W. C. Moore, 469
McKee, H. S : Root Parasites in Loranthaceae, 40
McKelvie, A. D. . Appointed plant physiologist, West African Cocoa Research Institute, Gold Coast, 695
MacKenzie, I. A. D. : Appointed assistant conservator of forests, Nigeria, 348
Mackenzie, Dr. J. E. : Honorary Fellowship of Heriot-Watt College, Edinburgh, conferred on, 142
Mackey, R. D. : Appointed lecturer in civil engineering at the University of Birmingham, 653
Mackie, H B An Education for a Pharmacist, 787
MacLaren, P. I. R. Appointed fisheries officer, Game and Tsetse Fly Department, Northern Rhodesia, 269
McLean, P. (Glock, Dr. G. E., and) Glucose-6-Phosphate Dehydrogenase Activity of Rat Liver, 119
McLean, Prof. R. C. · The University Training of a Botanist, 776
McLean, Prof. R C , and Ivimey-Cook, Dr. W. R. . Textbook of Theoretical Botany, Vol. I, *review* by Prof. Frank W. Jane, 257
MacLean, T. D. Awarded a Postgraduate Scholarship in Husbandry by the Department of Agriculture for Scotland, 784
McLeod, Dr. John : Spermatozoan Morphology, 232
McLeod, Prof. J. W. . Retirement from the Brotherton chair of bacteriology in the University of Leeds, 58 ; work of, 58
  Title of emeritus professor in the University of Leeds conferred on, 784
McLeod, T. S · Awarded a Radio Section Premium of the Institution of Electrical Engineers, 19
Macmillan, Lord : *Obituary*, 561
Macmillan, Dr. E. W. Spermatozoan Morphology, 232
Macmillan, R. H Energy in the Service of Man, 611
MacMullan, D. : Electron Microscopy of Solid Surfaces, 863
MacNalty, Sir Arthur International Health Organizations, 108
  Modern Methods in the Treatment of Tuberculosis, 609
  International Sanitary Regulations, 1107
McNeill, P. C . Awarded a British Thomson-Houston Engineering Research Fellowship, 59
Macowan, K. D. S. · Appointed deputy director of veterinary services, Kenya, 608
Macpherson, H. T. (Kemble, A. R , and) : Indicator Spray for Amino-Acids, 664
McRae, Dr. William : *Obituary* by Dr. R. S. Vasudeva, 561
Maddison, John Elected president of the International Scientific Film Association, 1006
Maes, H. . Phosphorus as a Factor Preventing DDT-Dehydrochlorination, 328
Magat, M. : Radiation Chemistry, 195
Magee, Dr. H. E. · Unusual Foods for Human Consumption, 1050
Magee, J. (Baxendale, J. H., and) : Reactivity of Free Radicals, 820
Magee, Prof. J. L. . Radiation Chemistry, 194
Magnes, J., and others : Survival of the Perfused Cat's Brain in the Absence of Glucose, 754
Mahajani, Dr. G. S. : Elected president of the Rajasthan Academy of Sciences, 406
Mahanta, P. C · Prospecting by Geophysical Methods, 230
Maheshwari, Prof. P. . Lysenko's Latest Discovery—The Conversion of Wheat into Rye, Barley and Oats, 66
Mainguy, M , and Grepin, A. Prospecting by Geophysical Methods, 231
Mainland, J. F , and Shaw, Dr. F. H. . Comparison of Ganglionic Blocking Agents, 418
Maize and Produce Organization, Kenya Appointment of Miss J. M. Slow as scientific officer, 269
Majury, T. G., and Steacie, E. W. R. · Reactivity of Free Radicals, 819
Makerere College—The University College of East Africa, 25
Makino, Dr. Katashi, and others Sex in *Pieris rapae* L. and the Pteridin Content of their Wings, 933
  Relation of 3-Hydroxykynurenine to the Ehrlich Diazo Reaction of Urine in Severe Tuberculosis, 977
Malek, S R. A. A Lipoprotein Precursor of Sclerotin in the Cockroach Cuticle, 850
Malina, Dr. Frank Biology and Productivity of Hot and Cold Deserts, 953
Maling, D. H · Awarded a Nature Conservancy Research Studentship in Physiography, 524
Malone, Thomas F. (edited by) : Compendium of Meteorology, *review*, 814
Malpress, Dr. F. H. (McGeown, Mary G., and) Synthesis of Deoxyribose in Animal Tissues, 575
Maltais, J B. (Auclair, J. L., and) : Occurrence of Gamma-Amino-Butyric Acid in Extracts of *Pisum sativum* (L.) and in the Honeydew of *Myzus circumflexus* (Buck.), 1114

Manchester Central Library : Industrial and Commercial Information Exhibition, 827
Manchester College of Technology : Appointment of Dr. H. N. Rydon to the chair of chemistry, 142
  Retirement of Prof. J. Hollingworth from the chair of electrical engineering, 185
  Appointment of Dr. Eric Bradshaw to the chair of electrical engineering, 185
  Jubilee Brochure, 1098
Manchester Museum : Sectional Model of the Earth in the, 523
  Annual Report for 1950–51, 563
Mandelbrot, Prof. B. : Applications of Communication Theory, 1052
Manners, D. J (Harrap, B. S., and) : Molecular Weight of Glycogens determined by a Light-scattering Method, 419
Mansbridge, Dr. Albert : Death of, 403
Mantell, G. A. (1790–1852), 782
Manton, Prof. Irene : The University Training of a Botanist, 775
Manton, Dr. S M. : Biology and Productivity of Hot and Cold Deserts, 952
Maple, E., and others   Dynamo Currents and Conductivities in the Earth's Upper Atmosphere, 1093
March, Prof Arthur . Quantum Mechanics of Particles and Wave Fields, *review* by Prof. G. Temple, 727
Mardles, Dr. E. W. J.   Plasticity of Materials, 876
Mardones, Dr. Elvira, and others . Structural Features of Antitumorigenic Corticoids, 917
Marfatia, Urmila, and others   A Sparing Effect by Formate or Methanol on the Impairment of Creatine Metabolism in Folic Acid Deficiency, 894
Margoliash, Dr. E. : Purification of Cytochrome c, 1014
Mari, Juan Llopis : Awarded a Ramsay Memorial Fellowship in Chemistry, 60
Marine Biological Association, Scottish : Annual Report and Collected Reprints, Nos. 57–87, 311
Marine Biological Association, Scottish, and others   International Seaweed Symposium, 478
Maritime Museum, National : Loaned an Elizabethan Lodestone by Lord Wharton, 562
Mark, H., and others   Copolymerization, *review* by Prof. H W. Melville, 1089
Marketing and Exports, Department of, Nigeria   Appointment of E G. Harmer as principal produce officer, 608
Markham, Dr Roy (Smith, Dr. J. D., and) : Polynucleotides from Deoxyribonucleic Acids, 120
Marks, E. (Crane, M. B., and) : Pear-Apple Hybrids, 1017
Marlier, Dr G. . Fish Feeding on *Simulium* Larvæ, 496
Marrack, Prof. J. R. : Title of professor emeritus of chemical pathology in the University of London conferred on, 228
Marriott, Dr. R. H. : Elected chairman of the Society of Cosmetic Chemists of Great Britain for 1952–53, 19
Marsh, C. A., and others   Glucuronide Decomposition in the Digestive Tract, 163
Marsh, Dr. Frank   Biology and Productivity of Hot and Cold Deserts, 953
Marsh, R. W.   Long Ashton Research Station—Open Day, 263
Marshall, Dr. A. J. : The Avian Pituitary, *review*, 553
Marshall, H. S. : History of Botanical Exploration in Malaysia, *review*, 336
Marshall, J. : New Research Techniques in Physics, 701
Marshall, J. C K. . Appointed conservator of forests, Federation of Malaya, 348
Marshall, K : Appointed prehistorian, Geological Survey Department, Uganda, 61
Marshall, Mrs. L. W. . New Research Techniques in Physics, 701
Marshall, Dr. P. R.   Determination of the Pore-Size Distribution in Porous Metal Bodies, 761
Marshall, W. A. . Awarded the Westinghouse Brake and Signal Co., Ltd , Prize of the Institute of Metal Finishing, 564
Marston, Hedley R., and Lee, H John   Cobalt in the Nutrition of Ruminants—Response of Cobalt-deficient Sheep to Massive Doses of Vitamin B_{12}, 791

Meadows, N. G. . Awarded a Radio Section Premium of the Institution of Electrical Engineers, 19
Mechanical Engineers, Institution of   Clayton Awards for 1952, 229
Mechanics (Theoretical and Applied), International Union of   Third General Assembly, 60
Medawar, Prof. P. B.   On Growing Old, *review*, 260
  Appointed a member of the Agricultural Research Council, 608
Medical Department, Tanganyika   Appointment of G Webbe as entomologist, 695
Medical Practitioners : World Congress of, for the Study of the Actual Conditions of Life, 739
Medical Research Council   Award of Rockefeller Travelling Fellowships in Medicine, 189
  Award of Eli Lilly Travelling Fellowships in Medicine, 189
  Award of Dorothy Temple Cross Research Travelling Fellowships in Tuberculosis, 189
  Award of Alexander Pigott Wernher Memorial Travelling Fellowships in Otology, 189
  Award of French Exchange Scholarships in Medical Science, 189
  Appointment of Dr J C. Gilson as director of the Pneumoconiosis Research Unit at Llandough Hospital, 484
  Appointment of Sir Geoffrey Vickers, Prof G. R. Cameron, Prof. A J Lewis and Sir James Spence as members, 524
  Kathleen Schlesinger Fellowship, 653
  Report for the Year 1950–51, 878
Medical Research Council (Committee on the Resettlement of the Disabled). Memorandum on Employment Problems of Disabled Youth in Glasgow, 833
Mees, Dr. C. E. Kenneth : Secrecy and Industrial Research, 972
Megaw, A. H S : Archæology in Cyprus 1951, 269
Meigh, Dr. D F. : Separation of the 2,4-Dinitrophenylhydrazones of Volatile Aldehydes and Ketones by Paper Chromatography, 579
Meigs, Prof. P. : Desert Research, 301
Meiklejohn, Dr. Jane : Minimum Phosphate and Magnesium Requirements of Nitrifying Bacteria, 1131
Meinesz, Prof. Vening : Prospecting by Geophysical Methods, 231
Meldahl, K. G   Tidal Forces in the Sun's Corona due to Planets, Part 3, 482
Mellanby, Sir Edward   Biochemistry and Biology of Antimetabolites, *review*, 429
Mellon Institute   Annual Report for 1951–52 (Edward R Weidlein), 410
  Research Proceedings of the, 1951–1952, 410
  Fellowship in Synthetic Organic Chemistry established by Parke, Davis and Co., Detroit, 484
Mellor's Modern Inorganic Chemistry, revised and edited by Dr. G. D Parkes, *review* by G. P., 511
Melville, George Fraser (the late)   Sum of £270,000 from the estate of, for the care and cure of cancer, 404
Melville, Prof. H. W. : Reactivity of Free Radicals—Faraday Society Discussion in Toronto, 819
  Copolymerization, *review*, 1089
Melville, Prof H W., and others   Self-branching of Vinyl Polymers, 1026
Mendel, Prof. B , and Myers, D. K.   Pseudo-Cholinesterase of Brain, 928
Mendel, Prof. B., and others   Oxidation of Thiophosphate Insecticides in the Rat, 805
Mendelssohn, K., and others .   Low Temperature Physics, *review* by S. Weintroub, 1088
Menger, Prof. Karl : You will like Geometry, 103
Menon, P. S. (Narayanan, E. K., and)   Enzymes of *Vibrio choleræ*, 621
Menter, Dr. J. W.   Electron Microscopy of Solid Surfaces, 862
  Applications of Photography to Research in the University, 880
Merlin, M., and others : Observations of a τ-Meson, 454
Metal Finishing, Institute of   Endowment of New Awards, 229
  Westinghouse Brake and Signal Co., Ltd , Prize awarded to W. A. Marshall, 564

Métallurgie, Société Française de : Autumn Meeting in Paris, 347
Metallurgists, Institution of : Presidential Address (Prof. Hugh O'Neill), 182
  Principles of the Extraction and Refining of Metals, 405
Metallurgists, Institute of, and others (Joint Committee on Metallurgical Education) : The Education and Training of Metallurgists, 989
Metals, Institute of : Students' Essay Prize for 1952 awarded to John C Wright, 61
  Students' Essay Prizes for 1953, 61
  Symposium on Properties of Metallic Surfaces, 442
  Election of Officers, 695
  Awards, 1098
Metals, Institute of, and others (Joint Committee on Metallurgical Education) : The Education and Training of Metallurgists, 989
Meteorological Society, Royal : Formation of the first Interest Group, 738
Meyer, K. : Physical Chemistry of Proteins, 520
Meyer-Eppler, Dr. W. : Applications of Communication Theory, 1052
Meyerhof, Dr G. G. : Plasticity of Materials, 876
Meynell, Sir Francis : The Chemistry of Cement, 785
Michelson, A. A. (1852–1931), 1001
Michie, Donald : A New Linkage in the House Mouse—Vestigial and Rex 585
Mickelsen, Olaf, and others : The Biology of Human Starvation, *review* by Dr. E. M Widdowson, 177
Middlesex Hospital Medical School : Appointment of Dr. Eric Neil to the University of London readership in physiology, 60
  Title of professor of pharmacology and therapeutics in the University of London conferred on Dr. C. A. Keele, 228
Middleton, Prof D. : Applications of Communication Theory, 1052
Midlands Society for Analytical Chemistry : Symposium on Analytical Chemistry, 307
Miettinen, Jorma K. (Virtanen, Prof. Artturi I., and) : Free Amino-Acids in the Leaves, Roots and Root Nodules of the Alder (*Alnus*), 283
Migeod, F. W. H. : *Obituary* by Dr. W. E Swinton, 184
Miles, Dr. A. A. : Appointed director of the Lister Institute of Preventive Medicine, 19, 57 ; work of, 57
Miles, V. G. : Radio Echoes and Lightning, 365
Military College of Science, Shrivenham, Wilts (Dr. O. G Sutton), 486
Millar, Dr. R. H. : Reversal of the Heart-beat in Tunicates, 851
Miller, A., and others : Enzymic Splitting and Synthesis of Glutathione, 841
Miller, F. : Appointed an agricultural officer, Gold Coast, 61
Miller, Miss F. C. : *Obituary* of Miss K C Boswell, 825
Miller, Hugh, 1802–56—Commemoration at Cromarty (Sir Edward Bailey), 790
Miller, J. J. (Adams, A. M., and) : Detection of Radiophosphorus in Cells and Spores of Fungi by Radioautography, 239
Miller, Dr N. : Radiation Chemistry, 195
Millor, R. : Appointed an agricultural officer, Nigeria, 60
Miller, W. A (Kinloch, D., and) : Gold Coast Timbers, revised edition, 563
Miller, William E. : Nominated president-elect of the British Institution of Radio Engineers, 308
Milling, B, and others : Action of X-Rays on Aqueous Solutions of Perchloric Acid, 710
Millott, Prof. N. : Colour Change in the Echinoid, *Diadema antillarum*, Philippi, 325
Mills, B Y. : Apparent Angular Sizes of Discrete Radio Sources—Observations at Sydney, 1063
Milne-Thomson, Prof. L. M. : Theoretical Aerodynamics, second edition, *review* by Prof. W. J. Duncan, 641
Milner, Henry B. : Sedimentary Petrography, third edition, *review*, 511
Milner, Prof. Max, and others : Internal Fissuring of Wheat due to Weathering, 533
Minder, Dr. W. : Radiation Chemistry, 196
Mineral Resources (Research) Committee, Uganda : Appointment of F. C. F. Wickery as technical assistant, 608
Mineralogical Society : Election of Officers for 1952–53, 829
Mining Engineers, Institution of : Election of J. Cecil Mitcheson as president for 1953–54, 100
Mining and Mechanical Engineers : The North of England Institute of (Prof. Granville Poole), 477
  Centenary of the foundation of the, 442
  Buddle Medal to be presented to Austin Kirkup, 442
Mining and Metallurgy, Institution of : Election of Prof. J. A. S Ritson as President, 651
  Sir Julius Wernher Memorial Lecture (Prof. A. M. Gaudin), 656
  Symposium on Mineral Dressing, 699
  H R.H The Duke of Edinburgh elected to honorary membership, 956
Mining and Metallurgy, Institution of, and others (Joint Committee on Metallurgical Education) : The Education and Training of Metallurgists, 989
Minnis, C. M. : E Region during the Solar Eclipse of February 25, 1952, 453
Mirza, Dr. Rafat : Reduction of Tropinone with Lithium Aluminium Hydride, 630
  Nature of the 'Induction Period' in the Preparation of Lithium Aluminium Hydride, 669
Misra, B. G., and others : Filarial Infections in Mosquitoes, 253
Mitchell, F. L. : Chromatographic Isolation and Estimation of the Natural Œstrogens from Tissue, 621
Mitchell, Prof. G. A G. : Rostral Extremities of the Sympathetic Trunks, 533
Mitchell, G. F. : Technical Aids in Archæology, 909
Mitchell, Prof. J S : Applications of Photography to Research in the University, 879
Mitchell, Dr R. G. : Awarded a Rockefeller Travelling Fellowship in Medicine by the Medical Research Council, 189
Mitcheson, J Cecil : Elected president of the Institution of Mining Engineers for 1953–54, 100 ; work of, 100
Mobbs, F R : Appointed lecturer in mechanical engineering at the University of Leeds, 784
Moewus, Dr Franz, and Moewus, Liselotte : Sensitivity of Cress Roots to Indole-Acetic Acid, 372
Mogey, J. M. : Resistance to Change in Farming, 689
Moissan, Henri (1852–1907), 522
Molière, G. : New Research Techniques in Physics, 701
Momber, E. W. : Appointed principal agricultural officer, Nigeria, 61
Moncrieff, R. W. : Artificial Fibres, *review*, 818
Mond Nickel Co., Ltd. : Endowment of the Hothersall Memorial Medal and Lecture of the Institute of Metal Finishing, 229
Monkhouse, Dr. A. C. : Coal, Coke and Coal Chemicals, *review*, 595
Monod, Prof. Th. : Desert Research, 301
  Biology and Productivity of Hot and Cold Deserts, 952
Moon, Dr. F. E. : Appointed senior lecturer in agricultural chemistry at the University of Glasgow, 913
Moon, J. T : Appointed assistant director of agriculture, Uganda, 61
Moore, F. W. (Bisset, Dr. K. A., assisted by) : Bacteria, *review* by Dr. S. T. Cowan, 133
Moore, G. S. : Applications of Photography to Research in the University, 879
Moore, W. C : Sugar Beet Diseases in Ireland, *review*, 469
Moorhouse, Dr. R. G. : The π^0-Meson, 513
Morales, M., and Botts, J. : Physical Chemistry of Proteins, 519
Moreton, B D. : Name this Insect, *review*, 595
Moreton, P. M. : Awarded a Clayton Fellowship of the Institution of Mechanical Engineers, 229
Morgan, A D. : Title of reader in morbid anatomy in the University of London conferred on, 229
Morgan, Dr C. Grey : Electrical Discharges in Gases, 601
Morgan, G T. : Farm Water Supplies, 1107
Morgan, Prof. W. T. J. (Gibbons, R A., and) : Serological Properties of Human Blood Group A and B Substances, 77
Mori, Itsuhiko, and others : Paper Electromigration of Flavonoids and Sugar using a High Constant-voltage Current, 975
Mori, Itsuhiko (Hashimoto, Dr. Yohei, and) : Ultra-Violet Papyrography—an Automatic Analytical Apparatus using Filter Paper without a Colour Reagent, 1024
Morozovitch, Paul, and others : Hypotensive Alkaloids of *Veratrum album*, 932
Morris, A. L., and others : Reactivity of Free Radicals, 820
Morris, C. E. H. : Awarded a Clayton Fellowship of the Institution of Mechanical Engineers, 229
Morris, T. R, and others : 'Infra-Red' Brooding and the Crooked-Toe Problem in Chicks, 167
Morrison, C J. : Appointed senior soil conservation officer, Jamaica, 61
Morrison, Miss Margaret T. : Appointed a lecturer in medical physics at the University of Leeds, 784
Morrison, R. B. : Appointed lecturer in bacteriology at the University of Glasgow, 19
Morrison-Scott, T. C. S. : A List of British Mammals, 188
  Degree of D Sc. of the University of London conferred on, 229
Morrison-Scott, T. C. S. (Ellerman, J. R., and) : Checklist of Palaearctic and Indian Mammals, 1758 to 1946, *review* by Dr. L. Harrison Matthews, 298
Mortlock, H. N., and Style, Dr. D W G. : Reaction between Diethyl Peroxide and Nitric Oxide, 706
Moss, Dr. A. A. : Preservation of a Saxon Wooden Bucket, 1002
Moss, G. (Rose, Dr. Horace E., and) : Streaming Potential and Electro-osmosis—A Model for the Mechanism of Streaming Potential, 836
Mostafa, Prof. M. A. : Carbohydrate Fermentation of Bacterial Isolates from Zygophyllaceous and Leguminous Root-Nodules, 276
Motokawa, Prof. Koiti, and Ebe, Mituru : Retinal Colour Processes caused by Intermittent White Light, 79
Mott, Prof. N. F. : Measurement and Importance of Elastic Properties of Metals, 528
Mousa, Dr. Tohamy A. : Senility Changes in the Spinal Ganglion Neurones of the Toad, *Bufo regularis*, 206
Moynahan, Dr. E. J : Cosmetics and Dermatitis, 22
Mrak, E. M., and Stewart, George F. (edited by) : Advances in Food Research, Vol. 3, *review* by A. T Parsons, 680
Muggleton, Dr. P. W. : The Standardization of Pertussis Vaccine, 236
Mulholland, P : Appointed an agricultural officer, Nigeria, 60
Muller, Dr. R. H. : Research in Analytical Instrumentation, 599
Mullink, J. A M. (Rottier, P. B., and) : Localization of Erythermal Processes caused by Ultra-Violet Light in Human Skin, 574
Mulvey, T. : German Society for Electron Microscopy—Fourth Annual Conference, 271
Mulvey, T. (Haine, M E., and) : Diffraction Microscopy with X-Rays, 202
Mumford, A. H. (Garratt, G. R. M., and) : The British Contribution to Television, 137
Mumford, Lewis : The Conduct of Life, *review* by R. Brightman, 1085
Murphy, D. H : Awarded a Nature Conservancy Research Studentship in Zoology, 524
Murray, A. K. : Appointed agricultural officer, Sierra Leone, 61
Murray, H. D. (edited by) : Colour, in Theory and Practice, new edition, revised, enlarged and re-written by R. Donaldson, V. J Francis, P. Holliday, R. G. Horner, N. Laycock, L C. Thomson, G. T. Winch and the editor, *review* by Dr. S. Clay, 859
Museum of Applied Science, Victoria : Annual Report for 1950–51, 347
Museum of Leathercraft, London : Establishment of a, 606
Museums Association : Annual Conference in Oxford, 354
Muskett, Prof. A E. : Botany of Flax, 558
Mutual Security Agency of the American Embassy : List of American Scientific Equipment for British Laboratories, 565
Myant, Dr N. B. : Awarded a Rockefeller Travelling Fellowship in Medicine by the Medical Research Council, 189
Mycological Society, British—Plant Pathology Field Day (R. V. Tipler), 409
Myers, D. K., and others : Oxidation of Thiophosphate Insecticides in the Rat, 805
Myers, D. K. (Mendel, Prof. B., and) : Pseudo-Cholinesterase of Brain, 928
Myers, G. E (Doty, P, and) : Physical Chemistry of Proteins, 518
Myers, Gordon S, and others : Hypotensive Alkaloids of *Veratrum album*, 932
Myers, K, and others : Myxomatosis in Australia—a Step towards the Biological Control of the Rabbit, 7
Myles, D. J. : Awarded a Clayton Fellowship of the Institution of Mechanical Engineers, 229
Myrback, Karl (edited by Sumner, James B, and) : The Enzymes, Chemistry and Mechanism of Action, Vol. 1, Parts 1 and 2, Vol. 2, Parts 1 and 2, *review* by A. L. Bacharach, 257

NAGELSCHMIDT, Dr. J. G.: Promoted a Senior Principal Scientific Officer in the Scientific Civil Service, 310
Nair, M. R. G. K., and others   Lipoid Solubility as a Factor in the Toxicity of Contact Insecticides, 619
Naismith, W. E. F. (Johnson, P., and)   Physical Chemistry of Proteins, 518
Nanninga, L. (Gorter, E., and)   Physical Chemistry of Proteins, 519
Napier, J. R: Appointed to the University of London readership in anatomy at the Royal Free Hospital School of Medicine, 19
Narayanan, E. K., and Menon, P. S   Enzymes of *Vibrio cholerae*, 621

  Retirement from the chair of natural history in the University of Edinburgh, 403 ; work of, 403
Ritson, Prof. J. A. S. : Title of professor emeritus of mining in the University of London conferred on, 228
  Elected president of the Institution of Mining and Metallurgy, 651 ; work of, 651
  Obituary of Prof. J. G. Lawn, 1046
Rizk, Dr. K. W. : Applications of Photography to Research in the University, 879.
Roach, W. H. G. : Fellowship of the City and Guilds of London Institute conferred on, 406
Roaf, Prof. H. E. : *Obituary*, 910
Robb, J. C., and others : Reactivity of Free Radicals, 820
Robb, J. G. : *Death* of, 1098
Robbins, Dr. William J., and others : Specificity of Vitamin B_{12} for *Euglena*, 845
Roberts, F., and Young, Prof. J. Z. : High-Speed Counting with the Flying-Spot Microscope, *erratum*, 19
  The Flying-Spot Microscope, 137
Roberts, G. E. : Awarded the Brabazon Premium of the British Institution of Radio Engineers, 308
Roberts, J., and others : Failure of Vacuum Insulation at Low Field Strengths, 503
Roberts, O. T. : Appointed agricultural officer, Kenya, 608
Roberts, P. J. P. (Whelan, Dr. W. J., and) : Action of Salivary α-Amylase on Amylopectin and Glycogen, 748
Roberts, R. (Darwent, B. de B., and) : Reactivity of Free Radicals, 820
Roberts, Sir Richard Lloyd : The Human Factor in Management, 66
Robertson, Dr. Alan (Carter, Dr. T. C., and) : Four-strand Crossing over, 986
Robertson, Prof. Alexander : Awarded the Davy Medal of the Royal Society, 826, 947 ; work of, 947
Robertson, Dr. Forbes W., and Reeve, Dr. E. C. R. : Heterozygosity, Environmental Variation and Heterosis, 286
Robertson, Dr. J. D. : Appointed a senior lecturer in zoology at the University of Glasgow, 19
Robertson-Cuninghame, R. C., and Blackman, Prof. G. E. : Effects of Preliminary Treatment on the Subsequent Variation in the Resistance of *Lemna minor* to the Phytotoxic Action of 2 : 4 Dichlorophenoxyacetic Acid, 459
Robin, G. de Q. : Awarded the Dr. W. S. Bruce Memorial Prize for 1952 of the Royal Society of Edinburgh, 61
Robins, W. H. M. : Measurement of Thicknesses of Fine Particles, 583
Robinson, Lord : *Obituary* by W. H. Guillebaud, 559
Robinson, Dr. A. A. : Awarded a Measurements Section Premium (Silvanus Thompson Premium) of the Institution of Electrical Engineers, 19
Robinson, J. B. D. : Appointed scientific officer, agricultural chemist, Kenya, 1003
Robinson, Dr. J. W. Dudley : Retirement as secretary of the Royal Sanitary Institute, 693 ; work of, 693
Robinson, K. L. : Antibiotics in Animal Nutrition, 869
Robinson, N. P. (Browne, Ian C., and) : Cross-polarization of the Radar Melting-Band, 1078
Robinson, R. A. : Appointed plant pathologist, Kenya, 348
Robinson, T. J. : Role of Progesterone in the Mating Behaviour of the Ewe, 373
Robinson, Alderman Wright : Associateship of the Manchester College of Technology conferred on, 651
Robson, G. R. : Appointed scientific officer, Trinidad, 695
Rockefeller Foundation : Gift of £870 to the Department of Botany, University of Leeds, 143
  A Review for 1950 and 1951 (Chester I. Barnard), 721, 963
  Grant of 12,000 dollars to the University of Oxford for research in the Department of Human Anatomy, 870
Rockefeller Foundation (Division of Medicine and Public Health) : Bursaries for Postgraduate Study and Research in Public Health Engineering, 189
Rodd, Dr. E. H. (edited by) : Chemistry of Carbon Compounds, Vol. I, Part A, *review*, 508
Roe, Frank Gilbert : The North American Buffalo, *review* by Dr. Maurice Burton, 945
Roff, H. E. : Ethics of Management, 102
Roger, J. Grant : *Diapensia lapponica* in Scotland, 783
Rogers, C. A. : Degree of D.Sc. of the University of London conferred on, 784
Rogers, Dr. W. P., and others : Biological Activity of Complex Ions, 190
Roget, S. R. : *Obituary* by J. F. Stanley, 1097
Rohatgi, Miss K. K. (Bowen, Dr. E. J., and) : Reactivity of Free Radicals, 820
Rollefson, Prof. G. K. : Radiation Chemistry, 195
Rollo, I. M. : 'Daraprim' Resistance in Experimental Malarial Infections, 415
Rollo, I. M. (Williamson, Dr. J., and) : Stimulating Effect of Amino-Acids on the Survival at 37° C. of *Trypanosoma rhodesiense* in a Serum-free Synthetic Medium, 376
Roper, Dr. J. A. (Heagy, Dr. F. C., and) : Deoxyribonucleic Acid Content of Haploid and Diploid *Aspergillus* Conidia, 713
Rorison, I. H. : Awarded a Nature Conservancy Research Studentship in Botany, 524
Rose, Dr. Horace E., and Moss, G. : Streaming Potential and Electro-osmosis—A Model for the Mechanism of Streaming Potential, 836
Rose, Dr. M. E. : Medium-Energy Nuclear Physics, 349
Rosenbach, Dr. O. : Prospecting by Geophysical Methods, 230, 231
Rosenfeld, Prof. L. : *Obituary* of Prof. H. A. Kramers, 99, *erratum*, 348
  Excited States of Light Nuclei, 512

Rosenstiel, Edwin : Deposition of Metal Films on Jelly-like Materials, 85
Ross, L M Insulation of Electrical Equipment, 1006
Ross, J G Appointed veterinary officer, Uganda, 608
Ross, J. K. : Appointed assistant conservator of forests, Nigeria, 695
Ross, Dr. M. A. S. (Ewan, Dr. George T., and) . γ-Rays of Radium-D, 760
Rossini, Prof. Frederic D. Chemical Thermodynamics, 732
Rostagni, A., and others Observations of a τ-Meson, 454
Rotblat, Prof Joseph : Degree of D Sc. of the University of London conferred on, 229
Rothschild, Miriam, and Clay, Theresa : Fleas, Flukes and Cuckoos, *review* by Dr. E. Hindle, 382
Rothwell, E Emulsions and Films, 233
Rottier, P B , and Mullink, J A M. . Localization of Erythermal Processes caused by Ultra-Violet Light in Human Skin, 574
Roughley, T C : Fish and Fisheries of Australia, revised edition, *review* by G. A Steven, 593
Rowe, E. G. : Awarded the Marconi Premium of the British Institution of Radio Engineers, 308
Roy, Radhagovinda, and others . Filarial Infections in Mosquitoes, 253
Roy, S K. (Krishnan, Sir K S , and) Polarization Field and the Acoustic Modes of Oscillation of Alkali Halide Crystals, 159
Royal Alfred Observatory, Mauritius Annual Report for 1950, 523
Royal Australian Chemical Institute H. G Smith Memorial Medal awarded to Prof. R J W. LeFèvre, 1049
Royal Entomological Society of London : Meeting to discuss the formation of a British branch of the Union Internationale pour l'Étude des Insectes Sociaux 61
Royal Free Hospital School of Medicine, London : Appointment of J R. Napier to the University of London readership in anatomy, 19
  Appointment of Dr. H. A B. Simons to the readership in physics, 269
Royal Greenwich Observatory Resumption of dropping the Time Ball, 738
  Annual Report for 1951–52, 1111
Royal Horticultural Society : Thirteenth International Horticultural Congress, 187
Royal Institute of Chemistry, and others Symposium on the Principles and Applications of Ion Exchange, 150
Royal Institute of Chemistry (London and South-Eastern Counties Section), and others Discussion on the Place of the Scientist in Civil Defence, 406, 957
Royal Institute of Philosophy Manson Lectures for 1952, 608
Royal Institution : Christmas Lectures for Juveniles (Dr. F Sherwood Taylor), 829
Royal Meteorological Society Formation of the first Interest Group, 738
Royal Observatory, Greenwich Resumption of dropping the Time Ball, 738
  Annual Report for 1951–52, 1111
Royal Observatory, Hong Kong Appointment of R F. Apps as scientific officer, 269
Royal Photographic Society . Ninety-seventh Annual Exhibition, 406, 609
  Centenary of the, 694
  International Conference on the Science and Applications of Photography, 694
  Christmas Lectures for Juveniles, 829
Royal Photographic Society (Scientific and Technical Group) Symposium on the Applications of Photography to Research in the University, 348, 879
Royal Sanitary Institute : Election of Lord Eustace Percy as president of the Health Congress to be held in 1953, 442
  Retirement of Dr. J. W. Dudley Robinson as secretary, 693
Royal Society . Discussion on the Structure of Proteins, 53
  Awards of Medals, 826, 870, 946
  Leeuwenhoek Lecture (Prof. A. J. Kluyver), 829
  Anniversary Address (Dr. E D. Adrian), 946
  Election of Officers and Council, 1049
Royal Society and the University of Cambridge Appointment of Dr. R. J. Eden as Smithson Research Fellow, 484
Royal Society of Arts : Albert Medal awarded to Sir Frank Whittle, 19
  Election of H R H. The Duke of Edinburgh as president, 829
  Centenary Number of the *Journal*, 1048
Royal Society of Canada—Meeting at Laval University, Quebec (Dr. B W. Sargent), 832
Royal Society of Edinburgh Dr. W S. Bruce Memorial Prize for 1952 awarded to G. de Q Robin, 61
  Presidential Address (Prof. James Kendall), 101
  Election of Officers, 739
Royal Swedish Academy of Engineering Sciences and the Association of Technical Physicists Conference on Instruments and Measurements, 145
Roylance, T F. : Awarded a Clayton Grant of the Institution of Mechanical Engineers, 229
Rubenstein, Albert H. (edited by Hertz, David B., and) Selection, Training and Use of Personnel in Industrial Research ; Proceedings of the Second Annual Conference on Industrial Research, June 1951, sponsored by the Department of Industrial Engineering, Columbia University, 941
Rubin, Mordecai (Wenkert, Dr. Ernest, and) Peroxidation of Unsaturated Ketones, 708
Rudall, Dr. K. M. The Structure of Proteins, 54
  Title and status of reader in biomolecular structure in the University of Leeds conferred on, 143
Rudra, Prof M. N. : Toxic Principle of *Lathyrus sativus*, 124
Rumford, Count (Benjamin Thompson) Celebrations of the bicentenary of the birth of (American Academy of Arts and Sciences), 954

  Appointment of Dr. M. M. Swann to the chair of natural history, 404
University of Edinburgh, and others: International Seaweed Symposium, 478
University of Glasgow: Appointment of G. Hoyle as lecturer in zoology, 19
  Appointment of R. B. Morrison as lecturer in bacteriology, 19
  Appointment of F. C. Flack as Imperial Chemical Industries, Ltd., research fellow in physics, 19, 913
  Appointment of Dr. M. F. Grundon and Dr. H. J. E. Lowenth
  Imperial Chemical Industries, Ltd., research fellows in chemistry, 19, 913
  Resignation of P. A. Sweet as lecturer in astronomy, 19
  Appointment of Dr. G. Pontecorvo as reader in gene
  Appointment of Dr. H. S. D. Garven as reader in h
  Appointment of J. R. Atkinson as senior lecturer i
  19
  Appointment of J. A. Downes and Dr. J. D
  lecturers in zoology, 19
  Appointment of Dr. L. D. Loudon and Dr. J.
  lecturers in chemistry, 19

  - Appointment of B. W. Ribbons as lecturer in botany, 19
  - Appointment of I C. Smith as lecturer in zoology, 19
  - Science in the, 913
  - Appointment of Dr. F. E. Moon as senior lecturer in agricultural chemistry, 913
- University of Hong Kong : Fisheries Research Unit of the, 789
- University of Leeds . Title and status of reader in zoology conferred on Dr. T. Kerr, 19
  - Leave of absence granted to Dr. R Brown as visiting professor at Cornell University, 19
  - Retirement of Prof. J. W McLeod from the Brotherton chair of bacteriology, 58
  - Appointment of Dr. C. L. Oakley to the Brotherton chair of bacteriology, 58
  - Gift from Johnson Bros. (Dyers), Ltd., Bootle, of an endowment fund of £2,000 to the Department of Colour Chemistry and Dyeing, 143
  - Gift of £870 from the Rockefeller Foundation to the Department of Botany, 143
  - Gift of additional equipment from the Turner Tanning Machinery Co , Ltd., to the Department of Leather Industries, 143
  - Gift of equipment from Barrow, Hepburn and Gale, to the Department of Leather Industries, 143
  - Gift of a machine from Baker Perkins, Ltd , Peterborough, to the Department of Leather Industries, 143
  - Appointment of Prof. D. Thoday as visiting professor in the Department of Botany, 143
  - Title and status of reader in biomolecular structure conferred on Dr. K. M Rudall and Dr. J MacArthur, 143
  - Report of the Librarian for the Session 1950–51, 483
  - Annual Report of the Brotherton Collection Committee for 1950–51, 607
  - Title of emeritus professor conferred on Prof. J W McLeod, 784
  - Appointment of Dr. R W Owen as lecturer in zoology, 784
  - Appointment of F. R. Mobbs as lecturer in mechanical engineering, 784
  - Appointment of G. Hay, G W. Reed and Miss Margaret T Morrison as lecturers in medical physics, 784
- University of Liège Degree of doctor of medicine *honoris causa* conferred on Prof Réné Fabre and on Prof. D. Keilin, 784
- University of London · Retirement of Sir David Brunt from the chair of meteorology and the post of head of the Department of Meteorology in the Imperial College of Science and Technology, 15
  - Appointment of P. A. Sheppard to the chair of meteorology, 16
  - Appointment of J. R. Napier to the University readership in anatomy at the Royal Free Hospital School of Medicine, 19
  - Degree of D Sc (Eng.) awarded to E C. Cherry, 19
  - Appointment of Dr. F. L. Warren to the University chair of biochemistry at London Hospital Medical College, 60
  - Appointment of Dr. Eric Neil to the University readership in physiology at Middlesex Hospital Medical School, 60
  - Appointment of Dr. W. S. Bullough to the University chair of zoology at Birkbeck College, 60, 142
  - Retirement of Prof. H E. Shortt from the University chair of medical protozoology at the London School of Hygiene and Tropical Medicine, 100
  - Appointment of Dr. P C. C. Garnham to the University chair of medical protozoology at the London School of Hygiene and Tropical Medicine, 100
  - Courses for the new degrees of B Sc (Nutrition) and B Sc (Household Science) at King's College of Household and Social Science, 226
  - Title of professor emeritus of bacteriology in the University conferred on Prof S. P. Bedson, 228
  - Title of professor emeritus of meteorology in the University conferred on Sir David Brunt, 228
  - Title of professor emeritus of chemical technology in the University conferred on Sir Alfred Egerton, 228
  - Title of professor emeritus of physical chemistry in the University conferred on Prof. G. I Finch, 228
  - Title of professor emeritus in chemical pathology in the University conferred on Prof. J. R. Marrack, 228
  - Title of professor emeritus in mining in the University conferred on Prof. J. A. S. Ritson, 228
  - Title of professor emeritus in physics in the University conferred on Sir George Thomson, 228
  - Title of reader in pharmacognosy in the University conferred on Dr. J. W Fairbairn, 228
  - Title of professor of pharmacology and therapeutics in the University conferred on Dr C. A. Keele, 228
  - Title of reader in biochemistry in the University conferred on Dr. William Klyne, 228
  - Title of reader in bacteriology in the University conferred on B W Lacey, 228
  - Title of professor of chemical pathology in the University conferred on N. H. Martin, 229
  - Title of reader in morbid anatomy in the University conferred on A D. Morgan, 229
  - Title of reader in structural geology in the University conferred on Dr Gilbert Wilson, 229
  - Degree of D.Sc. conferred on F. H. Burstall, P. C. C. Garnham, T. C. S Morrison-Scott, Prof. Joseph Rotblat, D. B. Scott and Prof. P. E. Vernon, 229
  - Engineering, Biophysics and Physics at King's College—New Building (Dr. M. H F. Wilkins), 261
  - Appointment of Dr. H. A. B. Simons to the readership in physics at the Royal Free Hospital School of Medicine, 269
  - Course of lectures on Nuclear Reactors at the City and Guilds College, 308
  - Seminar on Polymer Science in the Department of Chemistry, University College, 406
  - Celebration of the reconstruction of War-damaged Buildings of Bedford College for Women, 564
  - Appointment of Prof. Geoffrey Harris to the Fitzmary chair of physiology at Maudsley Hospital, 736
  - Title of reader in mechanical engineering conferred on H. Hampson, 784
  - Degree of D Sc. conferred on Miss Olive N. Purvis and C. A. Rogers, 784
  - Appointment of Dr. E. A. R. Braude to the University readership in organic chemistry at the Imperial College of Science and Technology, 829
  - Appointment of M. W Humphrey Davies to the University readership in electrical engineering at the Imperial College of Science and Technology, 829
  - Public Lectures to commemorate the granting of a Royal Charter to the School of Pharmacy, 829
  - Title of University reader in mechanical engineering conferred on Dr. William Davies, 956
  - Degree of D.Sc. conferred on Dan Lewis, 956
  - Appointment of Prof P M. S. Blackett to the University chair of physics at the Imperial College of Science and Technology, 1003
  - Title of reader in organic chemistry in the University conferred on Dr L. N. Owen, 1003
- University of London Institute of Education, and others Meeting on Food Science at Home and Overseas, 829
- University of Manchester Publications in Astronomy from the, 143
  - Retirement of Prof. J. Hollingworth from the chair of electrical engineering, 185
  - Appointment of Dr. Eric Bradshaw to the chair of electrical engineering, 185
  - Series I of the Astronomical Contributions, to be known as the *Jodrell Bank Annals*, 188
  - Retirement of Prof T. H. Pear from the chair of psychology, 440
  - Appointment of Dr John Cohen to the chair of psychology, 440
  - Exhibition in the Christie Library of the work on Logic of W. Stanley Jevons, 608, 696
  - Appointment of Jack Diamond to the first chair of mechanical engineering in the Faculty of Science, 953
- University of Otago Appointment of Michael Woodruff as Ralph Barnett professor of surgery, 605
- University of Oxford · Guinness Research Fellowships in Microbiological Biochemistry, 693
  - Grant of 12,000 dollars from the Rockefeller Foundation for research in the Department of Human Anatomy, 870
  - Grant of £1,500 a year for three years from the National Coal Board for research in the Department of Human Anatomy, 871
- University of Padua Gabriella Zuccari Scholarship, 442
- University of Paris Conferment of Honorary Degrees, 1048
- University of Pittsburg : The Origin and Development of the Allegheny Observatory (Theodore M. Lauterbach), 1008
- University of Pittsburgh . Conference on Medium-Energy Nuclear Physics, 349
- University of Reading Retirement of Prof. C H. O'Donoghue from the chair of zoology, 16
  - Appointment of Prof. A Graham to the chair of zoology, 16
- University of Rochester (National Science Foundation and the) Conference on High-Energy Nuclear Physics, 914
- University of Sheffield Appointment of F. T Williams as lecturer in the Postgraduate School of Mining, 145
  - Appointment of B. R Pursall as lecturer in the Department of Mining, 145
  - Appointment of P. H Price as lecturer in fuel technology, 145
  - Appointment of R. G. Siddall as research assistant to the professor of fuel technology, 145
  - Appointment of E. H Gillespie as honorary lecturer in bacteriology, 145
  - Resignation of Dr. B. Donovan as lecturer in physics, 145
  - Appointment of Dr. J. White as reader in ceramics, 956
  - Appointment of Dr A. S. Gladwin as lecturer in electrical engineering, 956
- University College of East Africa Makerere College—The, 25
- University College, Ibadan : Formal Opening, 1101
- University College, London . Seminar on Polymer Science, 406
  - Dinner to mark the centenary of Sir William Ramsay, 608
  - Sir William Ramsay and, 693
  - Gift of £2,700 annually from the Anglo-Saxon Petroleum Co , Ltd., to provide scholarships in chemical engineering, 829
- University College of North Staffordshire Appointment of Dr. A M. Macbeath as senior lecturer in mathematics, 653
  - Appointment of Dr. Monica M Cole as lecturer in geography, 653
  - Appointment of Miss Ruth M. Badcock and R L. Plack as lecturers in biology, 653
  - Appointment of Dr D. J. O'Connor as lecturer in philosophy, 653
  - Appointment of Mrs. P. Elizabeth Perrott as lecturer in education, 653
  - Appointment of Dr A. Frohlich and B. Noble as lecturers in mathematics, 653
  - Appointment of Dr. G. F. Smith as lecturer in chemistry, 653
  - Appointment of A. H Oliffe as lecturer in psychology, 653
  - Appointment of A. Hunter as assistant lecturer in economics, 653
  - Appointment of W. M. Williams as assistant lecturer in geography, 653
  - Appointment of Dr. S C. Nyburg as assistant lecturer in chemistry, 653
  - Appointment of Miss Helga M T Frankland as assistant lecturer in biology, 653
  - Appointment of P H. Shelford and A. F Trendall as assistant lecturers in geology, 653
  - Appointment of Sir John Lennard-Jones as principal, 912
- University College of the West Indies: Appointment of Dr. W. W Grave as principal, 226
- University Grants Committee Returns from Universities and University Colleges in receipt of Treasury Grant, Academic Year 1950–1951, 873

TITLE INDEX

ABDOMINAL Mechano-Receptors in *Dytiscus* and *Locusta* (G. M. Hughes), 531
Aberdeen · Chemistry in (Prof. R. M. Barrer), 741
Abnormal Leaves of *Cycas revoluta* Thunb. (Ramesh Kumar Srivastava), 253
Aboriginal Peoples in the British Commonwealth · Catalogue of an Exhibition illustrating the Medicine of the (Wellcome Historical Medical Museum), 273
Aboriginal Rain-Makers (Frederick D. McCarthy), 26
About (Edmond) and the Technique of Freezing and Drying Tissues (L. G. E. Bell), 547 ; (R. Legendre), 1080
Absence : Apparent, of Low-Energy Primary Cosmic Radiation (E. G. Dymond), 1078
Absorptiometer : New Biochem (Hilger and Watts, Ltd.), 694, 784
Absorption from Intestine of Rats with Blind Self-filling Pouch (D. W. Taylor), 81
Absorption Integral Determination of Neutron Resonance Parameters from Measurements of the—Application to the Main Resonance of Uranium-238 (G. v. Dardel and R. Persson), 1117
Absorption Spectra of Hæmoglobin and its Derivatives . Effect of Drying upon the (Prof. D. Keilin and Dr. E. F. Hartree), 161
Academic Freedom in the Modern State, 721
Accelerating Tubes . A Versatile Focusing System for van de Graaff (P. Howard-Flanders), 744
Accommodation : Eye Rotations with Change of (Dr. Mary P. Lord), 670
Accuracy and Sensitivity of the Human Eye (Dr. M. H. Pirenne and Dr. E. J. Denton), 1039
Acetate Metabolism in Ovine Ketosis (P. Storie Pugh and R. Scarisbrick), 978
Acetylating Proteins : A New Method for (Dr. J. Baddiley, Dr. R. A. Kekwick and Dr. E. M. Thain), 968
Acetylcholine Esterase of the White Components of Blood (Mrs. B. E. Hines), 78
Acid Salts of Monobasic Organic Acids—a New Series of Primary Standards for Alkalimetry (Dr. Neville Smith), 538
Acids (Monobasic Organic): Acid Salts of—a New Series of Primary Standards for Alkalimetry (Dr. Neville Smith), 538
Acinar Cell Necrosis subsequent to Ethionine · Rapid Restitution of the Rat Pancreas following (Dr. Patrick J. Fitzgerald and Dr. Mario Alvizouri), 929
Acoustic Modes of Oscillation of Alkali Halide Crystals . Polarization Field and the (Sir K. S. Krishnan and S. K. Roy), 159
Acrasieæ from Soil Samples : A New Method for Isolating Members of the (E. D. Kitzke), 284
Action of Agents giving Protection from Radiation : Mode of (Dr. P. Alexander and Dr. M. Fox), 1022
Action of Antibiotics : Mode of (Symposium on, at the Second International Congress of Biochemistry), 444
Action of Chloramphenicol . Mode of (Dr. Ernest D. Bergmann and Sarah Sicher), 931
Action of Mutagenic Reagents :- Site of—Nitrogen Mustards (Miss M. J. Ord and Prof. J. F. Danielli), 921 ; X-Rays (Dr. E. B. Harriss, Dr. L. F. Lamerton, Miss M. J. Ord and Prof. J. F. Danielli), 922
Activation of the Fluorescence of Chlorophyll Solutions (Prof. Robert Livingston and Sanford Weil), 750
Activation Energy and Frequency Factor : Relation between (Dr. M. Szwarc and D. Williams), 290
Adaptation of Bacteria against Quaternaries · Factors Governing the (R. Fischer and Dr. P. Larose), 715
Adaptive Mechanisms of Buffaloes to Ambient Temperature (Prof. A. L. Badreldin and M. A. Ghany), 457
Adenosine Triphosphate : Effect of the 'Marsh Factor' on the Shortening of Muscle Fibre Models in the Presence of (J. R. Bendall), 1058
Administration : The Art of (Ordway Tead), *review* by E. F. L. Brech, 430
Adrenal Cortical Hormones in Human Placenta (Constance de Courcy, Prof. C. H. Gray and J. Barbara Lunnon), 494
Adrenal Gland Homografts : Survival of, in the Rabbit's Skin (Dr. D. A. Darcy), 805
Adrenaline in Creams . The Assay of (Dr. G. F. Somers), 236
Adrenaline-Antidiuresis in the Water-loaded Dog (O. Eränkö and M. J. Karvonen), 331
Adsorption of Amino-acids on Sparingly Soluble Inorganic Solids (D. J. O'Connor and F. Bryant), 84
Adsorption of Cations by Metals : Demonstration by Radioactive Tracers of the (Prof. J. Palacios and A. Baptista), 665
Adventure : The Scientific (Prof. Herbert Dingle), *review* by F. I. G. Rawlins, 726
Aerobiology . Arctic—Fungi and Bacteria, etc., caught in the Air during Flights over the Geographical North Pole (Prof. Nicholas Polunin and Dr. C. D. Kelly), 314
Aerodynamics Theoretical (Prof. L. M. Milne-Thomson), second edition, *review* by Prof. W. J. Duncan, 641
Aeronautical Science and Engineering : Progress in (Sir Ben Lockspeiser), 396
Aeroplane Wings Shapes of, 697
Afforestation of Moorland (British Association for the Advancement of Science, Section K* (Forestry), Discussion on), 734
Africa : Contribution to the Ethnography of (Sture Lagercrantz), *review* by G. I. Jones, 993
Africa (British Central) : Seven Tribes of (edited by Elizabeth Colson and Max Gluckman), *review* by F. B. Steiner, 903
Africa (Central) . Higher Education in, 1001
  Mollusc Control and Fish-Farming in (Dr. A. F. De Bont and M. J. De Bont Hers), 323
Africa (East) : Groundnuts Scheme in, 782
  Makerere College—The University College of, 25
Africa (East and Central) : Education of Africans in (A. L. Binns), 399
Africa (Tropical) : Conference on Malnutrition in (Commission for Technical Co-operation in Africa South of the Sahara), 872
African Huts : Apparent Fumigant Action of Non-volatile Insecticides in (G. Davidson and G. F. Burnett), 893
African (South) Waters : Discovery of *Tetragonurus* Risso, 1810, in (Prof. J. L. B. Smith), 496
Africana Upsaliensia, *review* by G. I. Jones, 993
Africans in East and Central Africa · Education of (A. L. Binns), 399
Agar . Sodium Acetate, as a Sporulation Medium for Yeast (R. R. Fowell), 578
Age: Commentary on (Kenneth Walker), *review* by Prof. P. B. Medawar, 260
Ageing of Crystalline Precipitates (Prof. I. M. Kolthoff), 599
Agents giving Protection from Radiation Mode of Action of (Dr. P. Alexander and Dr. M. Fox), 1022
Ages Scientific Thought through the (Dr. Nazir Ahmad), 340
Agglutination Reactions in Human Red Cells fragmented by Heat (Ruth Ponder and Dr. Eric Ponder), 928
Aggregation : Micro-spherical, of Barium Sulphate (D. L. Stock), 423, *erratum*, 484
Agricultural Census in Iraq, 481
Agricultural Education (Minister of Agriculture and Fisheries Working Party on), 1049
Agricultural Phytopathology, *review* by Dr. S. G. Jones, 860
Agricultural Subjects : Postgraduate Scholarships in (Department of Agriculture for Scotland), 784
Agriculture Fellowships in Natural Science, Industrial Research, Virology and (British Memorial Fund in Victoria, Australia), 189
  Meteorology and (Sir Robert Watson-Watt), 738
  Reclaiming Land for (Moses Griffith, J. F. H. Thomas and R. Line), *review* by G. V. Jacks, 858
Agriculture (Colonial) : Statistics for (G. E. Hodnett), 26
Agriculture (Expanding) : Science and an (Sir William Slater), 432
Agriculture and Forestry, 562
Agrotis infusa Migration and Gregarious Æstivation in the Bogong Moth (I. F. B. Common), 981
Air . Arctic Aerobiology—Fungi and Bacteria, etc., caught in the, during Flights over the Geographical North Pole (Prof. Nicholas Polunin and Dr. C. D. Kelly), 314
Air Almanac, 1002
Air Masses over the British Isles : Characteristics of (Dr. J. E. Belasco), 27
Air-borne Allergens . Possible Role of Basidiospores as (Dr. P. H. Gregory and J. M. Hirst), 414
Airborne Dispersal of *Phytophthora palmivora*, causing Black-Pod Disease of *Theobroma cacao* (C. A. Thorold), 718
Aircraft (Supersonic) . The 'Double Bang' of (T. Gold), 808
Airman · Cartographical Needs of the, 783
Ajuan, Philippines : Silvicultural Observations in Cut-over Areas in (T. S. Serevo), 652
Albert Medal of the Royal Society of Arts awarded to Sir Frank Whittle, 19
Albumin (Plasma) : Reaction of Vitamin A Aldehyde with (K. Rajagopal and P. K. Datta), 370
Albumin Monolayers (Bovine Serum) : Ionization of (M. Z. Dogan and Dr. J. Glazer), 417
Alchemical Illustrations (Dr. F. Sherwood Taylor), 12
Alchemists : The (Dr. F. Sherwood Taylor), *review* by Dr. E. J. Holmyard, 725
Alchemy : New Light on, *review* by Dr. E. J. Holmyard, 725
Aldehydes : Thiol Catalysis of the Homolytic Decomposition of (Dr. E. F. P. Harris and Dr. W. A. Waters), 212
Aldehydes and Ketones (Volatile) : Separation of the 2,4-Dinitrophenylhydrazones of, by Paper Chromatography (Dr. D. F. Meigh), 579
Alder (*Alnus*) Free Amino-Acids in the Leaves, Roots and Root Nodules of the (Prof. Artturi I. Virtanen and Jorma K. Miettinen), 283
Algæ (Soil) . Counting, by Direct Fluorescence Microscopy (Y. T. Tchan), 328
Aliens (Indigent) · Study on Assistance to (Department of Social Affairs of the United Nations), 268
Aliens and Refugees . Indigent (Economic and Social Council of the United Nations Resolution on), 267
Alimentary Canal : Nervous Control of the Movements of the (Prof. R. C. Garry), 398
Alkali Halide Crystals · Polarization Field and the Acoustic Modes of Oscillation of (Sir K. S. Krishnan and S. K. Roy), 159
Alkalimetry : Acid Salts of Monobasic Organic Acids—a New Series of Primary Standards for (Dr. Neville Smith), 538
Alkaline Hypochlorite : Action of, on 3 : 5 . 6-Trimethyl-*d* gluconamide (Dr. K. S. Dodgson and Dr. J. Pryde), 35
Alkaline Phosphatase . Coupling Azo Dye Methods for Histochemical Demonstration of (Dr. E. Gregg and Dr. A. G. Everson Pearse), 578
Alkaloids · Solanaceous, in Normal and Grafted Plants (G. M. James and B. H. Thewlis), 1002
Alkaloids (Tropane) : Stereochemistry of the (Prof. G. Fodor), 278
Alkaloids of *Veratrum album* : Hypotensive (William L. Glen, Gordon S. Myers, Richard Barber, Paul Morozovitch and Gordon A. Grant), 932
6-*n*-Alkoxy-2-Naphthoic Acids: Influence of Substituents on the Mesomorphism of *p*-*n*-Alkoxybenzoic and (G. W. Gray and Prof. Brynmor Jones), 451
p-*n*-Alkoxybenzoic and 6-*n*-Alkoxy-2-Naphthoic Acids . Influence of Substituents on the Mesomorphism of (G. W. Gray and Prof. Brynmor Jones), 451

Alkyl Hydroperoxides : Preparation of (Dr. A. G. Davies and A. M. White), 668
Allergens (Air-borne) : Possible Role of Basidiospores as (Dr P. H. Gregory and J. M. Hirst), 414
Alloy Steel : Delayed Brittle Fracture of, at Low Stress Levels (C. L. M. Cottrell), 1079
Alloys : Research on the Constitution of (Constitution of Alloys Group of the British Iron and Steel Research Association), 305
Alloys (Copper Nickel) : Lattice Vacancies and Porosity in (Dr. E. C. Ellwood), 580
Almond Emulsin : Synthetic Action of (Prof. Stanley Peat, Dr. W. J. Whelan and Mrs K. A. Hinton), 1056
Alpha-Rays : Microradiography with (Gunnar Anansson and Naftali Steiger), 201
Alumines : Thermal Transformations of the, and their Hydrates (Margaret K. B. Day and Vernon J. Hill), 539
Alumni Cantabrigienses (compiled by Dr J. A Venn), Part 2, From 1752 to 1900, Vol. 4, Kahlenberg–Oyler, *review* by Prof. F. J. M. Stratton, 131
Alvarenga Prize for 1952 of the College of Physicians of Philadelphia awarded to Dr. Norbert Wiener, 348
America (Latin) International Laboratories in, 605
  Science in, 306
  Scientific Institutions and Scientists in (Unesco Science Co-operation Office for Latin America), Venezuela, Vol. 1, 306 ; Brazil, Vol. 3, 306
America (Western North) : Amphibians of (Robert C. Stebbins), *review* by Dr H. W. Parker, 768
American Farmer and his Woodlands, *review* by N D G. James, 551
American Scientific Equipment for British Laboratories, 566
American University : Graduate Study in an (United States Government and the Institute of International Education grants for), 269
American (Latin) Contribution to Scientific Progress—Chemistry, 1948–49 (Unesco Science Co-operation Office for Latin America), 306
American (North) Buffalo : The (Frank Gilbert Roe), *review* by Dr. Maurice Burton, 945
Amino-acids : Adsorption of, on Sparingly Soluble Inorganic Solids (D J. O Connor and P. Bryant), 84
  Hydrolysis and Metabolism by Soil Bacteria of Benzoyl Derivatives of D- and L-Forms of some (Prof. Yukio Kameda, Etsuko Toyoura, Hiroshi Yamazoe, Yukio Kimura and Yoshiro Yasuda), 888
  Indicator Spray for (A. R. Kemble and H. T Macpherson), 664
  New, in Young Apple Fruits (Dr. A. C. Hulme and W. Arthington), 659
  Stimulating Effect of, on the Survival at 37° C. of *Trypanosoma rhodesiense* in a Serum-free Synthetic Medium (Dr. J. Williamson and L M. Rollo), 376
Amino-Acids in the Leaves, Roots and Root Nodules of the Alder (*Alnus*) : Free (Prof. Artturi I. Virtanen and Jorma K. Miettinen), 283
Amino-acids in Legumes (Dr. N. G. Baptist), 76
Amino-acids and Peptides : Salting-out Chromatography of, in Filter Paper and other Media (L. Hagdahl and Prof A Tiselius), 799
Amino-Acids and Sugars: Use of *n*-Butanol–Formic Acid–Water Mixture in the Paper Chromatography of (Prof L. F. Wiggins and J. Howarth Williams), 279
Gamma-Amino Butyric Acid in Extracts of *Pisum sativum* (L.) and in the Honeydew of *Myzus circumflexus* (Buck.) : Occurrence of (J. L. Auclair and J. B. Maltais), 1114
Amphibians of Western North America (Robert C. Stebbins), *review* by Dr. H. W. Parker, 768
α-Amylase (Salivary): Action of, on Amylopectin and Glycogen (Dr. W. J Whelan and P. J. P. Roberts), 748
Amylopectin and Glycogen : Action of Salivary α-Amylase on (Dr. W. J. Whelan and P. J. P. Roberts), 748
Anaesthetic (Local) A New Type of (Emil Hofstetter), 980
Analogues of Cortisone : Simple (Dr. J. D. Billimoria), 248
Analyses of Several Sera Simultaneously : An Improved Electrophoresis Cell for the (Dr A. Polson), 628
Analysis : Microdiffusion, and Volumetric Error (Prof. Edward J Conway), third edition, *review* by A. L Bacharach, 5
Analysis (Qualitative Organic) : A Text-Book of Practical Organic Chemistry, including (Dr. Arthur I. Vogel), second edition, *review* by Prof. J. W. Cook, 727
Analysis (Quantitative Chemical) : A Basic Course in the Theory and Practice of (Prof. George L. Clark, Prof. Leonard K. Nash and Prof. Robert B. Fischer), *review*, 727
Analysis by Diffusion, *review* by A. L. Bacharach, 5
Analysis of Experiments : The Design and (Prof. Oscar Kempthorne), *review* by Dr D. J. Finney, 991
Analysis of Heavy Water : Physical Properties and (Isidor Kirshenbaum), edited by Harold C. Urey and George M. Murphy, *review* by Prof. H. J. Emeléus, 635
Analytical Apparatus using Filter Paper without a Colour Reagent : Ultra-Violet Papyrography—an Automatic (Dr. Yohei Hashimoto and Itsuhiko Mori), 1024
Analytical Instrumentation Research in (Dr. R. H. Muller), 599
Anatomical Distinction between Human and Pig Strains of *Ascaris* (Dr J. F. A Sprent), 627
Anatomical Nomenclature, 186
Anatomy (Human) : Atlas of (Franz Frohse, Max Brodel and Leon Schlossberg), new edition, *review* by Prof. W. J. Hamilton, 178
Anatomy of Metabolism in Higher Plants (Prof. Meirion Thomas), 359
Ancestors Embryos and (G. R. de Beer), revised edition, *review* by Prof. S. Zuckerman, 5
Anglo-American Relations in the Atomic Age (Dr. James B Conant), 215
Angular Distribution of the Neutrons from the Reaction ^{7}Li(*d*,*n*)^{8}Be (Prof. B. Trumpy, T Grotdal and A. Graue), 1118
Angular Momentum in Dirac's New Electrodynamics (R W. Iskraut), 1125
Angular Sizes Apparent, of Discrete Radio Sources—Observations at Jodrell Bank, Manchester (R. Hanbury Brown, R. C Jennison and M. K. Das Gupta), 1061 ; Observations at Sydney (B. Y. Mills), 1063 ; Observations at Cambridge (F G. Smith), 1065
Animal (Aquatic) A Simple Device for measuring the Volume of an (Dr. C. P. Gnanamuthu), 587
Animal Fats : Evolution of (Dr. F. B. Shorland), 924 ; (Prof. T. P. Hilditch), 925
Animal Nutrition : Antibiotics in (British Association for the Advancement of Science, Sections I (Physiology) and M (Agriculture), Discussion on), 868
Animal Tissue Isolation of a Soluble Fibrinolytic Activator from (Dr. Tage Astrup and Agnete Stage), 929
Animal Tissues : A Substance in, which stimulates Ketone-Body Excretion (H. B. Stewart and Prof. F. G. Young), 976
  Suramin (Bayer 205) in—Demonstration of Bayer 205 (Suramin) in Tissues and its Cellular Distribution ; Visual Demonstration of Immune Reactions in Tissue (Prof. N Jancsó and Dr. A Jancsó-Gábor), 567, 568
  Synthesis of Deoxyribose in (Mary G. McGeown and Dr. F. H. Malpress, 575
Animal Viruses : Contrasting Methods of Transmission of, by Mosquitoes (Prof Frank Fenner and Dr. M. F. Day), 204
Animal and Plant Protein Feeds A Difference in *in vitro* Pancreatic Digestion between (Dr A. Bondi and Mrs. Yehudith Birk), 673
Animals Parasitic (Dr Geoffrey Lapage), *review*, 218
Animals (Farm) : A Fauna of, *review* by Dr. John Hammond, 260
Anisotropy (Crystal) : A New Method of Melting Ferromagnetic Semi-conductors—BaFe$_{18}$O$_{27}$, a New Kind of Ferromagnetic Crystal with (H P. J. Wijn), 707
Annals and Magazine of Natural History : To combine with the *Journal of Botany*. 405
Annealed Mild Steel under Static and Dynamic Conditions : Work-hardening of (A. W Crook), 1124
Anomalous Specific Heat of Chromium Oxide (Cr_2O_3) at the Antiferromagnetic Curie Temperature (Dr. J. Volger), 1027
Antagonistic Effects of Cortisone and Salicylate (M J H. Smith), 240
Anthrone Reagent : Determination of Yeast Carbohydrates with the (W. E. Trevelyan, R S. Forrest and J. S. Harrison), 626
Anthropological Studies of Arab Life, *review* by Dr. J. C. Trevor, 638
Anthropology : A Hundred Years of (T. K. Penniman), second edition, *review* by Dr R. F. Fortune, 1037
Anthropology (Social) : Moral Philosophy and, *review* by Lord Raglan, 174
Anthropology during the Past Century, *review* by Dr R. F. Fortune, 1037
Antibiotic Substances : Production of, by the Roots of a Grass (*Trachypogon plumosus* (H. B K.) Nees) and of *Pentanisia variabilis* (E. Mey.) Harv. (Rubiaceae), (Gordon Stiven), 712
Antibiotics : Mode of Action of (Symposium on, at the Second International Congress of Biochemistry), 444
  Hormones, Chemotherapy and, *review* by Prof. J. W. Cook, 1086
Antibiotics in Animal Nutrition (British Association for the Advancement of Science, Sections I (Physiology) and M (Agriculture), Discussion on), 868
Antibody (Homologous Rabbit) : Inhibition of Lysine Decarboxylase from *E coli* by (Arthur F. Howe and Prof Henry P Treffers), 123
Anticholinesterases (British Pharmacological Society and the Fine Chemicals Group of the Society of Chemical Industry Symposium on), 1100
Antiferromagnetic Curie Temperature Anomalous Specific Heat of Chromium Oxide (Cr_2O_3) at the (Dr. J. Volger), 1027
Antifungal Polypeptide produced by *Bacillus subtilis* (J. Babad, A. Pinsky, R. Turner-Graff and N. Sharon), 618
Antigen A (Bovine Erythrocyte) : Correlation Study of, and Butterfat Test (T J McClure), 327
Anti-malarial Drug, 'Daraprim'. A New (Burroughs Wellcome and Co), 17
Antimetabolites : Biochemistry and Biology of, *review* by Sir Edward Mellanby, 429
  A Study of (D. W. Woolley), *review* by Sir Edward Mellanby, 429
Antimony-124 and Iodine-131 : Scintillation Spectrometer Studies on the Decay Schemes of Silver-110, (S. Almqvist and Sven A. E. Johansson), 583
Anti-mutagens (Aaron Novick and Leo Szilard), 926
Antitubercular Agents : New Hydroxamic Acids as (Prof. T Urbanski, S. Hornung, S. Slopek and J. Venulet), 753
Antitumorigenic Corticoids Structural Features of (Dr. Elvira Mardones, Dr. R. Iglesias, Dr. F Fuenzalida, Dr. S. Bruzzone and Prof. A. Lipschutz), 917
Ants, Bees and Termites Behaviour of (British Association for the Advancement of Science, Section D (Zoology), Discussion on), 642
Apatite : Growth Spirals and their Relation to Crystal Habit as Illustrated by (S. Amelinckx), 760
Aphids : A New Approach to the Problems of the Spread of, and to Insect Trapping (Dr. C. G. Johnson), 147
Apparatus : A Simple, for Measuring Potential Evapotranspiration (Prof. B. J. Garnier), 286
Apple and the Spectroscope (T. R. Henn), *review* by H. H T., 684
Apple Fruits (Young) : New Amino-Acids in (Dr. A. C. Hulme and W. Arthington), 659
Apple-Snail, *Pila globosa* (Swainson) : Uricotelism in the Common Indian (Dr. M. B. Lal and B. B. Saxena), 1024
Aqueous Media : Synthesis of Diphosphopyridine Nucleotide by Cell Nuclei isolated in (Dr. George G. Hogeboom and Dr. Walter C. Schneider), 374
Aqueous Solutions of Perchloric Acid Action of X-Rays on (B. Milling, Dr. G. Stein and Dr. J. Weiss), 710
Aqueous Solutions of Radioactive Isotopes : Luminescence of, and the Cerenkov Effect (Dr. E. H. Belcher), 571
Arab Life : Anthropological Studies of, *review* by Dr. J. C. Trevor, 638
Arabia : Wild Life in (Desmond Foster-Vesey-Fitzgerald), 238
Arable Crop Experimentation : The Practice of (P. N. Harvey), *review*, 1038
Arable Husbandry : Experimental Methods in, *review*, 1038
Arabs : Birth and Childhood among the (Dr. Hilma Granqvist), *review* by Dr J. C. Trevor, 638
  Child Problems among the (Dr. Hilma Granqvist), *review* by Dr. J. C. Trevor, 638
Archaeological Sites : Time and Trace Metals in (V. P. Sokoloff and G. F Carter), 872
Archaeology : Technical Aids in (British Association for the Advancement of Science, Section H (Anthropology and Archaeology), Discussion on), 909
Archaeology in Cyprus, 1951 (A. H. S. Megaw), 269
Archaeology in Greece, 1950–51 (J M. Cook), 269
Archaeology of the Santa Elena Peninsula in South-west Ecuador (G. H. S. Bushnell), *review* by Miss B. M. Blackwood, 51
Archaeology, Folklore and Sacred Tradition (Prof. E O. James), 397
Arctic Aerobiology—Fungi and Bacteria, etc., caught in the Air during Flights over the Geographical North Pole (Prof. Nicholas Pol and Dr. C. D. Kelly), 314

Arctic or Sub-Arctic Research . Fellowship and Scholarships for work on (McGill University and the Arctic Institute of North America), 695
Argon (Liquid) : Viscosity and Thermal Conductivity of (Prof. E. N. da C. Andrade), 794
Arid Zone · Hydrology of the (Unesco, with the Government of Turkey, Symposium on), 300
Arid Zone Research (Dr H. C Thornton), 300 , (Prof. S Goldstein), 300
    Meeting in London of the Advisory Committee on, 1103
Arid Zones Power Sources in (Advisory Committee on Arid Zone Research of Unesco Meeting to discuss), 523
Arizona Flora of, *review* by Sir Edward Salisbury, 299
Arizona Flora (Thomas H Kearney, Robert H. Peebles and collaborators), *review* by Sir Edward Salisbury, 299
Aroylacrylic Acids . A Novel Synthesis for (Martin Goldman and Ernest I Becker), 35
Arsen (Gmelins Handbuch der anorganischen Chemie, achte Auflage, System-Nummer 17), *review*, 902
Arsenic Acid and Dichlorophenoxyacetic Acid Phytotoxicity of Histamine, and Methods of Testing (C. G. Greenham), 535
AsH Band Spectrum of (S M. Naudé and T J Hugo), 289
Art of the Blind . Psychology and (Prof G. Revész), *review* by Prof. John Cohen, 815
Artefacts in the Chromatography of Tissue Extracts containing Inorganic Iodide A Possible Source of (J. D Acland), 32
Arthropods Body-Temperature of (Dr. E B Edney), 586
Artificial Cellulose Fibres Occurrence of Small angle X-Ray Diffraction Maxima in some (D Heikens, P H. Hermans and A. Weidinger), 369
Artificial Fibres (R W. Moncrieff), *review*, 818
Artificial Satellite The (edited by L J Carter), 486
Ascaris Anatomical Distinction between Human and Pig Strains of (Dr J F. A Sprent), 627
Asclepiadaceae . An Atlas of the (Prof. R. Good), 783
Ascorbic Acid . Identification of Uric Acid and, by Chromatography (Dr F. Bode and H. J. Hubener), 501
Ash Pictures in the Identification and Assay of Vegetable Drugs (Prof Goeta Edman), 954
Ash and Clinker in Industry (T. F. Hurley) 999
Asia (South-East) Scientific and Technical Periodicals published in (Unesco East Asia Science Co-operation Office), 59
Asparagine in Glycyl-L-Asparagine Configuration of the Peptide Link and of (Dr Lewis Katz, R A Pasternak and Prof. Robert B. Corey), 1066
Aspergillus (Heterozygous Diploid) . Non-random Distribution of Multiple Mitotic Crossing-over among Nuclei of (Dr G Pontecorvo), 204
Aspergillus Conidia (Haploid and Diploid) Deoxyribonucleic Acid Content of (Dr. F C. Heagy and Dr J. A. Roper), 713
Assay of Vegetable Drugs : Ash Pictures in the Identification and (Prof. Goeta Edman), 954
Assessment of Personality (Prof. P. E. Vernon), 398
Astrometry of Faint Stars (International Astronomical Union Symposium on), 786
Astronautics Third International Congress on, 348 ; (J. Humphries), 1053
    Proceedings of the Second International Congress on (edited by L. J. Carter), 486
l'Astronomie · Two accounts of the Eclipse of the Sun at Khartoum, 914
Astronomy Chaucer's (Dr. Derek J. Price), 474
    Publications in, from the University of Manchester, 143
Atkinson (Llewellyn B.) Premium of the Institution of Electrical Engineers awarded to Dr. H L Haslegrave, 19
Atlantic Seismic Refraction Shooting in the (M N Hill and J. C Swallow), 738
Atlantic Coast (Western) : Life of the, *review* by Dr D P. Wilson, 640
Atlas of the Asclepiadaceae (Prof. R Good), 783
Atmosphere . Scintillation of Stars and the, 305
Atmosphere (Earth's Upper) Dynamo Currents and Conductivities in the (Dr S. F. Singer, E. Maple and W. A. Bowen, jun.), 1093
Atmosphere near the Ground · Spore Content of the (P H Gregory), 475
Atmospheric Pressure Systems · Behaviour of (T. Schumann), 1077
Atmospheric Seeing Scintillation and (H. E. Butler), 305
Atom Bomb British (National Committee of Science for Peace Statement on), 606
Atomic Age Anglo-American Relations in the (Dr. James B. Conant), 215
Atomic Collision Processes, *review* by Prof H. W B. Skinner, 901
Atomic Mass Measurements : Evidence for Nuclear Shells from (Prof. Henry E. Duckworth), 158
Atomic Nuclei Statistical Theory of (Prof P Gombás), 362
Atomic Nucleus and its Constituents (Prof R. E Peierls), 524
Atoms · Forbidden Transitions in (A. G Shenstone), 832
Atoms (Recoil) . Decomposition of Organic Matter by, from an Adjacent Phase (D F. Sangster and J. Wright), 368
Atoms to Stars · From (Dr. Martin Davidson), third edition, *review* by F M. Holborn, 596
Atoms and Axiology, *review* by F I. G Rawlins, 591
Aurorae Theories of Magnetic Storms and (Dr. J W Dungey), 795
Aurorae over the British Isles : Appeal for co operation in the survey of (James Paton), 829
Auroral Hydrogen Lines Enhancement of, towards Lower Latitudes (Prof. L. Vegard), 1120
Auroral Spectrograms taken in Rapid Succession · Great Intensity Variations of Hα and Effects in (Prof. L. Vegard), 536
Australia Fish and Fisheries of (T. C. Roughley), revised edition, *review* by G. A. Steven, 593
    Government Research in—Commonwealth Scientific and Industrial Research Organization, 565
    Myxomatosis in—a Step towards the Biological Control of the Rabbit (F. N Ratcliffe, K Myers, B. V. Fennessy and J H Calaby), 7
Australia (South) From Black to White in (Ronald and Catherine Berndt), *review* by D'Arcy Ryan, 551
Authority and Responsibility, 1
Autographs (Sheep Skin) Spread of Pigment in (Dr. Margaret H Hardy, Dr. A. S. Fraser and Dr. B. F. Short), 849
Automatic Analytical Apparatus using Filter Paper without a Colour Reagent · Ultra-Violet Papyrography—an (Dr. Yohei Hashimoto and Itsuhiko Mori), 1024
Automatic Particle-Sizing by Successive Countings (P G. W Hawksley), 984
Autonomic Ganglion Depressant Properties of Barbiturates (K. A. Exley),242
Autoradiography : Improvements to the Melted Emulsion Technique of (Prof Leonard F. Bélanger), 625
Autoradiography of Metal Surfaces using a Radiochemical Method (E. Rabinowicz), 1029
Autoxidative Reactions—their Chemistry, Mechanisms and Catalysis by Metal Salts (Prof C. E H. Bawn), 653
Avian Coccidiosis · Lowered Liver Vitamin A Reserves in (Alan W. Davies), 849
Avian Pituitary The Structure and Development of the, from a Comparative and Functional Viewpoint (Karl Georg Wingstrand), *review* by Dr. A J. Marshall, 553
Aviation (British) . Survey of (*The Times*), 441
Axes (Stone) Petrological Identification of, 828
Axillary Buds in Jute (*Corchorus capsularis*) Origin and Development of (Dr B C. Kundu and N S Rao), 1128
Axiology Atoms and, *review* by F. I G Rawlins, 591
'Azidine' Transformation (F L. Scott, A Koczarski and Prof J Reilly), 922
Azo Dye Methods for Histochemical Demonstration of Alkaline Phosphatase . Coupling (Dr. E Grogg and Dr. A G Everson Pearse), 578

BACILLUS subtilis An Antifungal Polypeptide produced by (J. Babad, A Pinsky, R. Turner-Graff and N Sharon), 618
    Preparation of Crystals containing the Plakalbumin forming Enzyme from (A V. Guntelberg and M. Ottesen), 802
Backward Countries Development of, 677
Bacteria (Dr K. A. Bisset, assisted by F. W. Moore), *review* by Dr. S T Cowan, 133
    Factors Governing the Adaptation of, against Quaternaries (R. Fischer and Dr. P. Larose), 715
    A Natural History of, *review* by Dr. S. T Cowan, 133
    Soil, and Chlamydospore Formation in *Fusarium solani* (C S. Venkat Ram), 889
Bacteria (Nitrifying) Minimum Phosphate and Magnesium Requirements of (Dr Jane Meiklejohn), 1131
Bacteria (Soil) · Detoxication of Hormone Herbicides by (Dr H L Jensen and H. Ingv Petersen), 39
    Hydrolysis and Metabolism by, of Benzoyl Derivatives of D- and L Forms of some Amino acids (Prof. Yukio Kameda, Etsuko Toyoura, Hiroshi Yamazoe, Yukio Kimura and Yoshiro Yasuda), 888
Bacteria, etc., caught in the Air during Flights over the Geographical North Pole Arctic Aerobiology—Fungi and (Prof Nicholas Polunin and Dr. C. D Kelly), 314
Bacterial Growth Factor Synthesized by a Soil Bacterium (A. G Lochhead, Margaret O Burton and R. H Thexton), 282
Bacterial Invasion (H A Druett), 288
Bacterial Isolates from Zygophyllaceous and Leguminous Root Nodules Carbohydratic Fermentation of (Prof M A. Mostafa), 276
Bacteriology in Leeds, 58
Bacteriophage Nucleic Acids · A New Pyrimidine Base from (Dr G R. Wyatt and Dr S. S. Cohen), 1072
Bacteriophages (*Staphylococcus aureus*), Group G . A New Serological Division of (Joan E. Rippon), 287
Bacterium (soil) A Bacterial Growth-Factor Synthesized by a (A G. Lochhead, Margaret O Burton and R H. Thexton), 282
Bacup, Lancashire A Ligulate Pteridophyte from the Lower Coal Measures of (Dr H. Duerden and A S Wright), 41
Balneologie der Thermen Grundriss zu einer (Prof. Vale Vouk), *review*, 134
Bamboo Hybrids . Sugarcane × (T S. Raghavan), 329
Band Spectrum of AsH (C. M Naudé and T. J. Hugo), 289
Barbiturates . Autonomic Ganglion Depressant Properties of (K A. Exley), 242
Barbituric Acids Paper Chromatographic Separation of (Dr. Arne Grieg), 845
$BaFe_{12}O_{19}$ Crystal Structure of (Dr. P B. Braun), 708
$BaFe_{12}O_{19}$, a New Kind of Ferromagnetic Crystal with High Crystal Anisotropy : A New Method of Melting Ferromagnetic Semiconductors —(H. P. J Wijn), 707
$(Ba,H_2O)_2Mn_5O_{10}$ Role of Water in the Structure of Psilomelane, (A D. Wadsley), 973
Barium Sulphate . Micro-spherical Aggregation of (D. I. Stock), 423, *erratum*, 484
Barley (Potassium-deficient) Occurrence of Putrescine in (F. J. Richards and R G Coleman), 460
Barley and Oats : Lysenko's Latest Discovery—The Conversion of Wheat into Rye, (Prof P Maheshwari), 66
Barnacles (Intertidal) Changes in the Distribution of the, in relation to the Environment (A J Southward and D J Crisp), 416
Bars Effect of Variation in Diameter on the Torsional Vibration of (H. Pursey), 502
Basidiomycete occurring in England . *Corticium praticola* Kotila, an Interesting (N. T. Flentje), 892
Basidiospores as Air-borne Allergens . Possible Role of (Dr. P. H Gregory and J. M. Hirst), 414
Bauschinger Effect in Metals · Magnetic Properties, Internal Strains and the (D. V. Wilson), 30
Bayer 205 (Suramin) in Animal Tissues—Demonstration of Bayer 205 (Suramin) in Tissues and its Cellular Distribution , Visual Demonstration of Immune Reactions in Tissue (Prof. N Jancso and Dr. A. Jancso-Gábor), 567, 568
Bee (Honey-) Colony · New Evidence of Communication in the (C. R. Ribbands, Dr. H. Kalmus and H. L. Nixon), 438
Beeches (New Guinea and New Caledonian) Identification of Tertiary Pollen Grains with those of (Dr. Isabel C. Cookson), 127
Bees and Termites Behaviour of Ants, (British Association for the Advancement of Science, Section D (Zoology), Discussion on), 642
Behavior The Organization of, a Neuropsychological Theory (Prof. D. O. Hebb), *review* by Prof John Cohen, 297
Behaviour (Crowd) On the Objective Study of (Dr. L. S. Penrose), *review* by Prof. John Cohen, 472
Behaviour (Human) Factors influencing Change in, 688
Behaviour of Ants, Bees and Termites (British Association for the Advancement of Science, Section D (Zoology), Discussion on), 642
Behaviour of Atmospheric Pressure Systems (T. Schumann), 1077
Behaviour of Bower-Birds (Prof. Evelyn Hutchinson), 110 , (Dr. L. Harrison Matthews), 269

Behaviour of Fertilized Rabbit Eggs exposed to Glycerol and to Low Temperatures (Dr. A. U Smith), 374
Behaviour of a Synthetic Polypeptide analogous to Protein Denaturation (Dr A Elliott), 1066
Bell (Jacob) Memorial Scholarship of the Pharmaceutical Society awarded to T. M. French, 346
11 12-Benzfluoranthene · Isolation of, from a Coal Tar Fraction (A. S. Harris), 461
Benzoyl Derivatives of D- and L-Forms of some Amino-acids Hydrolysis and Metabolism by Soil Bacteria of (Prof. Yukio Kameda, Etsuko Toyoura, Hiroshi Yamazoe, Yukio Kimura and Yoshiro Yasuda), 888
Beta Radioactivity, 514
Beta-Rays Intensification of the Latent Photographic Image produced by (Prof. K. Zuber), 669
Beta- and Gamma-ray Radioactivity (Netherlands Physical Society, the International Union of Pure and Applied Physics, and Unesco, Conference on), 229
Betatron and Conventional X-Radiation . Relative Biological Effectiveness of, on the Regression of Mouse Tumours (Dr. T. F King, Dr H. E Jones and Prof L B Jaques), 752
BHC and Dieldrin . Experiments on the Use of DDT, against Adult Mosquitoes at Taveta, Kenya (G. Davidson), 702
Bibliographical Digest French, No. 7, Physics, No 8, Chemistry, 227
Bibliographies in the Library of the Faculty of Agronomy and Veterinary Science of the University of Buenos Aires Compilation of the (Ministry of Education of the Argentine), 306
Bibliography British National, Annual Volume 1951 (edited by A J. Wells), *review*, 595
Bifrost Temporary Reversal on, *review* by N W Pirie, 92
Bigsby Medal for 1952 of the Geological Society of London awarded to Prof. K C Dunham, 1098
Bilston Glen Preservation of Geological Sites—, 855
Bioassay of Cholinesterase Inhibitors A New Method for the (S. Callaway, P. Dirnhuber and K. M. Wilson), 843
Biocatalyseurs · Les (Prof. Max-Fernand Jayle), Tome I, Enzymes, substrats, vitamines et hormones, *review*, 178
Biochem Absorptiometer New (Hilger and Watts, Ltd.), 694, 784
Biochemical Differences between Red and White Muscle (R. A. Lawrie), 122
Biochemical Genetics Human (British Association for the Advancement of Science, Sections D (Zoology), I (Physiology), J (Psychology) and K (Botany), Discussion on), 654
Biochemistry . Second International Congress of, 443
Biochemistry (Microbiological) . Guinness Research Fellowships in (University of Oxford), 693
Biochemistry of Hæmopoiesis (Symposium on, at the Second International Congress of Biochemistry), 443
Biochemistry and Biology of Antimetabolites, *review* by Sir Edward Mellanby, 429
Biogenesis of Proteins (Symposium on, at the Second International Congress of Biochemistry), 443
Biographical Essays Philosophical and, *review* by Prof. A D Ritchie, 992
Biological Activity Ionization, pH and (Dr. H C. S Wood), 994
Biological Activity of Complex Ions (Dr F. P. Dwyer and Dr Eleonora C. Gyarfas, Dr W P Rogers and Dr Judith H Koch), 190
Biological Activity of some Enteramine-related Substances (Dr. V. Erspamer), 281
Biological Activity of 2 · 3 5 . 6-Tetrachloronitrobenzene and its Isomers · Differences in the (M. Brook), 1022
Biological Assessment of Chemotherapeutics, 235
Biological Conference Copenhagen, 23
Biological Control of the Rabbit Myxomatosis in Australia—a Step towards the (F N. Ratcliffe, K. Myers, B V Fennessy and J H. Calaby), 7
Biological Effectiveness Relative, of Betatron and Conventional X-Radiation on the Regression of Mouse Tumours (Dr. T. P. King, Dr. H E. Jones and Prof L. B. Jaques), 752
Biologically Significant Macromolecules (British Association for the Advancement of Science, Section B (Chemistry), Discussion on), 690
Biology Marine, in Scotland, 311
Biology at Chelsea Polytechnic, London, 870
Biology as a Career (Institute of Biology Discussion on), 189
Biology of Antimetabolites Biochemistry and, *review* by Sir Edward Mellanby, 429
Biology of Hot Springs, *review*, 134
Biology of Human Starvation (Ancel Keys, Josef Brozek, Austin Henschel, Olaf Mickelsen, Henry Longstreet Taylor), *review* by Dr. E M. Widdowson, 177
Biology of Proteins . Chemistry and (Prof. Felix Haurowitz), *review* by Dr R L. M. Synge, 6
Biology of Social Behavior Mathematical (Nicolas Rashevsky), *review* by E. Grebenik, 3
Biology and Productivity of Hot and Cold Deserts (Institute of Biology Symposium on), 951
Biophysics . Some Researches on (edited by Y Asami), 482
Biophysics and Physics at King's College, London Engineering,—New Building (Dr. M H. F Wilkins), 261
Biosynthesis of Carotenes in Ripening Tomatoes (Dr. T. W. Goodwin and Malini Jamikorn), 104
Biosynthesis of Vitamin C and a New Precursor (Prof. M C. Nath, R. P Chitale and Miss Bhavani Belavady), 545
Bird Conservation in Europe, 97
Bird Finding East of the Mississippi A Guide to (Olin Sewall Pettingill, Jr.), *review*, 52
Bird Lover's Week-End Book (Eric Hardy), *review* by Frances Pitt, 684
Bird Parasites, *review* by Dr. E. Hindle, 382
Birds Homing Ability in (G. V. T. Matthews), 237 ; (Gustav Kramer), 237
Birds (Bower-) : Behaviour of (Prof Evelyn Hutchinson), 110 , (Dr. L Harrison Matthews), 269
Birds (British) : The Pocket Guide to (R S R. Fitter), *review* by R. M. Lockley, 944
Birds of the Channel Islands (Roderick Dobson), *review*, 769
Birds of Greenland, *review* by Sir Norman Kinnear, 639
Birds of Kashmir Breeding (Lieut -Colonel R S P. Bates and E H. N. Lowther), *review*, 511
Birefringence of Myosin Changes in the Flow, as a result of Muscular Atrophy (Georges Schapira, Jean-Claude Dreyfus and Maurice Joly), 494
Birth and Childhood among the Arabs (Dr. Hilma Granqvist), *review* by Dr. J. C. Trevor, 638
Bitter Principle from Jute Seeds (*Corchorus capsularis*, Linn) Corchsularin, a New (M A. Kalique and M Ahmed), 1019
Black to White in South Australia From (Ronald and Catherine Berndt), *review* by D'Arcy Ryan, 551
Black-Pod Disease of *Theobroma cacao* Airborne Dispersal of *Phytophthora palmivora*, causing (C. A. Thorold), 718
Blind . Psychology and Art of the (Prof. G. Révész), *review* by Prof. John Cohen, 815
Blocking Agents (Ganglionic) : Comparison of (J. F. Mainland and Dr. F. H. Shaw), 418
Blocking Substances (Neuro-Muscular) . Motor End-Plate Differences as a Determining Factor in the Mode of Action of (Dr. Eleanor J Zaimis), 617; (H. C Churchill-Davidson and A. T. Richardson), 617
Blood Acetylcholine Esterase of the White Components of (Mrs. B. E. Hines), 78
Blood (Shed) Relationship between Reduced Glutathione Content and Spontaneous Hæmolysis in (Dr. G. Fegler), 624
Blood Group *A* and *B* Substances (Human) . Serological Properties of (R A. Gibbons and Prof. W. T J. Morgan), 77
Blood Group Antigens and the Presence of anti-*O* or anti-*H* in Human Serum A Relationship between the Secretion of the (Dr Ruth Sanger), 78
Blood Goups The Human (Dr F Stratton), 821
  Totem Poles and (Prof. R. Ruggles Gates), 377; (G. H. S. Bushnell), 377
Blood Picture of Cattle Diurnal Variations in the (R N. T.-W.-Fiennes), 934
Blood Pressure of Normal Rats : Effect of Cortisone on the (C. Bertazzoli, Prof. C Cavallero and G. Sala), 43
Blood Sub-Groups A_1, A_2 and A_1B, A_2B Relationship of the, to Hæmagglutinins present in the Seeds of *Dolichus biflorus* (Lieut.-Colonel G. W. G Bird), 674
Blood and Urinary Glycoproteins . Sugar Components of—Confirmation of the Presence of Fucose by a New Reaction (Dierdre M. Waldron), 461
Blue Sun of September 1950 (R Wilson), 103 , (E. M. Elsley), 103
Body Relation between Total and Exchangeable Sodium in the (Dr. R E. Davies, H L. Kornberg and Dr G M. Wilson), 979
Body Fluids Progesterone in (D. G Edgar), 543
Body-Temperature of Arthropods (Dr E. B Edney), 586
Bogong Moth, *Agrostis infusa* Migration and Gregarious Æstivation in the (I. F. B. Common), 981
Bond Dissociation Energies Heats of Formation of Mercury Dimethyl, Diethyl and Diphenyl and some associated (A. S Carson, Mrs. E. M. Carson and B. Wilmshurst), 320
Books Recent Scientific and Technical, Supp. vi, July 26 ; Supp iii, August 30 ; Supp. vi, September 27 , Supp. vi, October 25 ; Supp. v, November 29 , Supp vi, December 27
  Spanish Scientific (Science Museum Exhibition), 739, 828
Borehole . Gravity Observations in a (R. L. G. Gilbert), 424
Born Approximation in Electron Diffraction (Prof Verner Schomaker and Dr Roy Glauber), 290
Boron for *Nostoc muscorum* Necessity of (Clyde Eyster), 755
Botanical Aspects of the Form Problem, *review* by Prof. Edmund W Sinnott, 990
Botanical Exploration in Malaysia : History of, *review* by H. S Marshall, 336
Botanical Teaching and Training · University, 770
Botanist The University Training of a (British Association for the Advancement of Science, Section K (Botany), Discussion on), 770
Botany, Journal of · The *Annals and Magazine of Natural History* to combine with the, 405
Botany (Theoretical) · Textbook of (Dr. R. C. McLean and Dr. W. R. Ivimey-Cook), Vol I, *review* by Prof. Frank W. Jane, 257
Botany for the Degree Student, *review* by Prof Frank W. Jane, 257
Botany of Flax (British Association for the Advancement of Science, Section K (Botany), Discussion on), 557
Botany of Sugarcane (Dr. C van Dillewijn), *review* by Prof. C. W. Wardlaw, 640
Bovine Casein · Isolation of Phosphothreonine from (C -H de Verdier), 804
Bovine Erythrocyte Antigen A and Butterfat Test Correlation Study of (T. J McClure), 327
Bovine Serum Albumin Monolayers . Ionization of (M. Z. Dogan and Dr. J Glazer), 417
Bovine Tuberculosis in Denmark and its Eradication The Campaign against (T. Mathiassen), 102
Bower-Birds Behaviour of (Prof Evelyn Hutchinson), 110 ; (Dr. L Harrison Matthews), 269
Brabazon Premium of the British Institution of Radio Engineers awarded to G. E Roberts, 308
Brahe's (Tycho) Supernova (A.D. 1572) · Radio-Frequency Radiation from (R. Hanbury Brown and C. Hazard), 364
Brain . Pseudo-Cholinesterase of (Prof. B. Mendel and D. K. Myers), 928
Brain (Cat's) . Survival of the Perfused, in the Absence of Glucose (A. Geiger, J Magnes and R. S. Geiger), 754
Breakdown of Pentose Phosphates by Liver Fractions . Formation and (Dr. Gertrude E. Glock), 162
Breeding of Cultivated Plants · The Origin, Variation, Immunity and (Selected writings of N I. Vavilov), translated from the Russian by Dr K. Starr Chester, *review* by Prof S. C. Harland, 48
Breeding Biology of the Spotted Flycatcher (D. Summers-Smith), 607
Brewery Convention, European—Proceedings of the Congress, Brighton, 1951, *review* by Dr E Barton-Wright, 901
Bridge of Life, from Reality to Mystery (Dr. Augusto Pi Suñer), *review* by N. W Pirie, 92
Britain Contributors to Experimental Physics from (Prof. A. M Tyndall), 393
  Control of Public Expenditure in, *review* by R. Brightman, 337
  Distribution of Research Effort in, 465
  Electrical Engineering in, 874
  Technical and Technological Education in, 765
  Utilization of Fuel in, 589
  See also under Great Britain
Britain's Food Supplies (Dr. N. C. Wright), 400
British Amateur Ornithologist's Vade-Mecum, *review* by R. M. Lockley, 944
British Atom Bomb (National Committee of Science for Peace Statement on), 606
British Aviation : Survey of (*The Times*), 441

TITLE INDEX

British Birds : The Pocket Guide to (R. S. R. Fitter), *review* by R. M. Lockley, 944
British Central Africa . Seven Tribes of (edited by Elizabeth Colson and Max Gluckman), *review* by F. B. Steiner, 903
British Colonial Territories, 1951–52, 303
British Colonial Territories Library Services in the (Lionel R. McColvin), 169
British Commonwealth : Catalogue of an Exhibition illustrating the Medicine of the Aboriginal Peoples in the (Wellcome Historical Medical Museum), 273
  Universities of the, *review*, 133
British Contribution to Television (Institution of Electrical Engineers Convention on), 136
British Electronic Instruments in Research and Industry (Scientific Instrument Manufacturers' Association of Great Britain Symposium on), 877
British Industry Joint Consultation in (Report of an Inquiry undertaken by the National Institute of Industrial Psychology), 255
  Research and Development in the, a Survey of Expenditure on Industrial Research and Development in the Year 1950–51 (Industrial Research Committee of the Federation of British Industries), 465
British Insect Pests . Common Names of, 346
British Isles Appeal for co-operation in the survey of Aurora over the (James Paton), 829
  Characteristics of Air Masses over the (Dr. J. E. Belasco), 27
  The Freshwater Life of the (John Clegg), *review* by H. C. Gilson, 681
British Journal of Applied Physics (edited by Dr. H. R. Lang), Vol. 2 and Supplement No. 1, 1951, *review*, 473
British Laboratories : American Scientific Equipment for, 566
British Mammals : A List of (T. C. S. Morrison-Scott), 188
British Memorial Fund in Victoria Fellowships in Natural Science, Industrial Research, Virology and Agriculture, 189
British National Bibliography Annual Volume, 1951 (edited by A. J. Wells), *review*, 595
British Ornithological Conference, 227
British Pharmaceutical Codex 1949, Supplement 1952 (Pharmaceutical Society of Great Britain), *review*, 818
British Pharmaceutical Conference, 1952 (C. B. Challen), 787
British Standard of Radioactive Iodine (^{131}I) (Dr. E. C. Bullard), 916 ; (Dr. Henry Seligman and John L. Putman), 917
British Students Fellowships to, for Advanced Study and Travel in the United States (Commonwealth Fund of New York), 524
British Trade Unions : The Government of (Dr. Joseph Goldstein), 812
British Waters Copepods New to (R. V. Gotto), 674
  The Stauromedusan *Craterolophus tethys* Clark in (Dr. F. Segrove), 1023
Brittle Fracture of Alloy Steel Delayed, at Low Stress Levels (C. L. M. Cottrell), 1079
Broadcasting Conference European, at Stockholm, 185
Broadcasting Services Overseas Information and (Foreign Office Committee on), 738
Broadcasting and Television since 1900 (Maurice Gorham), 47
Broadcasting and Television in Great Britain, 45
Bromine-82 . Permeability of Yolk of the Hen's Egg to (D. M. Maurice and A. Fidanza), 546
Bruce Memorial Prize for 1952 of the Royal Society of Edinburgh awarded G. de Q. Robin, 61
Buchanan Medal of the Royal Society awarded to Sir Rickard Christophers, 826, 948
Bucket Preservation of a Saxon Wooden (Dr. A. A. Moss), 1002
Buddle Medal of the North of England Institute of Mining and Mechanical Engineers to be presented to Austin Kirkup, 442
Buds (Axillary) Origin and Development of, in Jute (*Corchorus capsularis*), (Dr. B. C. Kundu and N. S. Rao), 1128
Buffalo The North American (Frank Gilbert Roe), *review* by Dr. Maurice Burton, 945
Buffalo (Indian Water) Chromosomes of the (M. K. Dutt and P. Bhattacharya), 1129
Buffaloes Adaptive Mechanisms of, to Ambient Temperature (Prof. A. L. Badreldin and M. A. Ghany), 457
Bufo regularis Senility Changes in the Spinal Ganglion Neurones of the Toad (Dr. Tohamy A. Moussa), 206
Burning Determination of the Velocity of (Dr. J. van Steenis), 1068
Bursaries for Postgraduate Study and Research in Public Health Engineering (Division of Medicine and Public Health of the Rockefeller Foundation), 189
n-Butanol–Formic Acid–Water Mixture : Use of, in the Paper Chromatography of Amino-Acids and Sugars (Prof. L. F. Wiggins and J. Howarth Williams), 279
Buthus quinquestriatus (H. E.) Development of the Embryonic Coverings in the Scorpion (Dr. A. Abdel-Wahab), 209
Butter-fat irradiated with High-energy Electrons An After-effect in (R. S. Hanna and H. J. Shepherd), 1021
Butterfat Test Correlation Study of Bovine Erythrocyte Antigen A and (T. L. McClure), 327
tert-Butyl Group . Steric Effect of the (Dr. Malcolm Crawford and F. H. C. Stewart), 322
Butyric Acid Relief of Hypoglycaemic Convulsions with (B. J. Potter), 541

CACAO Collecting Expedition to Colombia (Imperial College of Tropical Agriculture and the Government of Colombia), 441
Caesium Chloride . Electrical Conductivity of, near the Thermal Transition (W. W. Harpur and Prof. A. R. Ubbelohde), 975
Calculation of the Internal Surface of a Lung (H. Campbell and Dr. S. I. Tomkeieff), 117
Callitriche intermedia Variation in Leaf Form in (Herbert Jones), 848
Callus (Fern) *In vitro* Cultures of a (Taylor A. Steeves and I. M. Sussex), 672
Calotes versicolor Preserved in Formalin : Viability of *Conspiculum guindiensis* in (N. G. S. Rahgavan), 125
Cambridge Men More Old, *review* by Prof. F. J. M. Stratton, 131
Camera (Gamma-Ray Pinhole) Use of, for *in vivo* Studies (H. O. Anger), 200
Cancer Research at Edinburgh on, 404
Cancer in London : A Survey of (Dr. W. L. Harnett), *review* by Dr. I. Donrach, 220
Cancer in London during 1938–39 : Survey of, *review* by Dr. I. Donrach, 220
Cancer Research : Progress of, 515
'Capacitation' of the Mammalian Sperm (C. R. Austin), 326
Carbamido Acid from Autolysed Yeast : Isolation of a (Prof. W. R. Fearon and Dr. W. A. Boggust), 372
Carbide : A New Molybdenum (K. Kuo and G. Hagg), 245
Carbohydrate Residue of a Urine Mucoprotein inhibiting Influenza Virus Haemagglutination (Dr. Alfred Gottschalk), 662 ; (Dr. L. Odin), 663
Carbohydrates (Yeast) Determination of, with the Anthrone Reagent (W. E. Trevelyan, R. S. Forrest and J. S. Harrison), 626
Carbohydrates in Saccharomyces Proximity of Genes controlling the Fermentation of similar (Prof. Carl C. Lindegren and Gertrude Lindegren), 965
Carbohydratic Fermentation of Bacterial Isolates from Zygophyllaceous and Leguminous Root-Nodules (Prof. M. A. Mostafa), 276
Carbon Compounds Chemistry of (edited by Dr. E. H. Rodd), Vol. 1, Part A, *review*, 508
Carbon Dioxide in *Chlorella* Rate of Photosynthesis and Concentration of (Dr. C. P. Whittingham), 1017
Carbon Dioxide Production : Detection of Insects by their (R. W. Howe and T. A. Oxley), 562
Carbon Monoxide Effect of Water Vapour on Explosions of (D. E. Hoare and Dr. A. D. Walsh), 838
Carbonic Anhydrase Inhibition : Inhibition of Gastric Secretion of Hydrochloric Acid *in vivo* by (Henry D. Janowitz, Henry Colcher and Franklin Hollander), 499
Carboxylase Essential Role of Thiol Groups in (Prof. A. O. M. Stoppani, A. S. Actis, Dr. J. O. Deferrari and Dr. E. L. Gonzalez), 842
Carboxypeptidase on Tobacco Mosaic Virus Action of (Dr. J. Ieuan Harris and Dr. C. A. Knight), 613
Carcinogenic Chemical Compounds Extension of the *K*-Region Hypothesis of (E. C. Kooyman and I. W. Heringa), 661
Career : Biology as a (Institute of Biology Discussion on), 189
Carotenes in Ripening Tomatoes Biosynthesis of (Dr. T. W. Goodwin and Malini Jamikorn), 104
Cartographical Needs of the Airman, 783
Casein (Bovine) Isolation of Phosphothreonine from (G.-H. de Verdier), 804
Cast Irons : Crystal Distortion of Graphite in (Eitaro Matuyama), 1123
Castor Oil Plant *Ricinus communis* : Pulps for Writing and Printing Papers from the (Dr. R. V. Bhat and Narendra S. Jaspal), 28
Cat's Brain : Survival of the Perfused, in the Absence of Glucose (A. Geiger, J. Magnes and R. S. Geiger), 754
Catalysis : Heterogeneous (Discussions of the Faraday Society, No. 8), *review* by Prof. J. R. Partington, 944
  Thiol, of the Homolytic Decomposition of Aldehydes (Dr. E. F. P. Harris and Dr. W. A. Waters), 212
Cathode-Ray Oscilloscopes and their Uses Encyclopedia on (John F. Rider and Seymour D. Uslan), *review* by G. E. Ashwell, 684
Cations Demonstration by Radioactive Tracers of the Adsorption of, by Metals (Prof. J. Palacios and A. Baptista), 665
Cattle Diurnal Variations in the Blood Picture of (R. N. T.-W.-Fiennes), 934
  Methane Fermentation in the Rumen of (W. H. Beijer), 576
Cattle in Denmark : Eradication of Bovine Tuberculosis from, 102
Cell Division : Formation of New Cell Walls in (Dr. A. B. Wardrop), 329
Cell Nuclei isolated in Aqueous Media . Synthesis of Diphosphopyridine Nucleotide by (Dr. George H. Hogeboom and Dr. Walter C. Schneider), 374
Cell Surface Constituents and Yeast Flocculation (Wold. Lindquist), 544
Cell Wall of *Micrococcus lysodeikticus* as the Substrate of Lysozyme (M. R. J. Salton), 746
Cell Walls Formation of New, in Cell Division (Dr. A. B. Wardrop), 329
Cells (Single) Transplantation of Mouse Sarcoma with Small Numbers of (H. B. Hewitt), 622
Cellular Permeability of Yeast to Metallic Ions (E. Quagliozzi and A. Rescigno), 35 ; *erratum*, 103
Cellulose Microbial Decomposition of (R. G. H. Siu), *review*, 594
Cellulose Fibres (Artificial) Occurrence of Small-angle X-Ray Diffraction Maxima in some (D. Heikens, P. H. Hermans and A. Weidinger), 369
Cement : Chemistry of (Cement and Concrete Association in conjunction with the Building Research Station of the Department of Scientific and Industrial Research Symposium on), 347, 785
Cement Research : Laboratories for, 270
Centaurus, Vol. 1, Nos. 3 and 4, Vol. 2, No. 1, 186
Centipedes : Epidermal Glands in (Gordon Blower), 166
Central Africa : Education of Africans in East and (A. L. Binns), 399
  Higher Education in, 1001
  Mollusc Control and Fish-Farming in (Dr. A. F. De Bont and M. J. De Bont Hers), 323
Central Africa (British) Seven Tribes of (edited by Elizabeth Colson and Max Gluckman), *review* by F. B. Steiner, 903
Centrifuges and pH Meters (Institute of Biology Survey of), 229
Cerastium Basic Chromosome Numbers in the Genus (Olive E. Brett), 251
Cereal Seeds : X-Ray and Neutron Mutagenic Effects on, 1112
Cerenkov Effect : Luminescence of Aqueous Solutions of Radioactive Isotopes and the (Dr. E. H. Belcher), 571
Change Resistance to (British Association for the Advancement of Science, Section J (Psychology), Discussion on), 688
Change of Accommodation Eye Rotations with (Dr. Mary P. Lord), 670
Change in Farming . Resistance to (British Association for the Advancement of Science, Sections J (Psychology) and M (Agriculture), Symposium on), 688
Change in Human Behaviour : Factors influencing, 668
Channel Islands The Birds of the (Roderick Dobson), *review*, 769
Character (Acquired) Selection of the Genetic Basis for an (Prof. Paul G. 'Espinasse), 71
Charophyte A Lower Devonian (W. N. Croft), 1002
Chaucer's Astronomy (Dr. Derek J. Price), 474
Chayen Process for Extraction of Oils and Fats (Dr. J. M. Coulson), 881
Chemical Analysis A Contemporary Assessment of the Place of Classical Methods in (Prof. van Nieuwenburg), 599
Chemical Analysis (Quantitative) A Basic Course in the Theory and Practice of (Prof. George L. Clark, Prof. Leonard K. Nash and Prof. Robert B. Fischer), *review*, 727
Chemical Analysis in Industry and Manufacture . The Value and Economic Importance of (Dr. L. H. Lampitt), 599
Chemical Basis of Morphogenesis (Dr. A. M. Turing), 955
Chemical Composition of Mammalian Sperm (R. Duncan Dallam and Prof. Lloyd E. Thomas), 377

- Chemical Compounds (Carcinogenic) Extension of the *K*-Region Hypothesis of (E. C Kooyman and J W. Heringa), 661
- Chemical Differentiation of the Genera *Podocarpus* and *Dacrydium* (the late C. W. Brandt and B. R. Thomas), 1018
- Chemical Engineering Education and Training in (British Association for the Advancement of Science, Section G (Engineering), Discussion on), 644
  - European Congress for (To be made a permanent annual feature), 61
  - Scholarships in (Anglo-Saxon Petroleum Co , Ltd.), 829

- Chromatography (Filter Paper) Application of Material in (Prof. U S. von Euler and R. Eliasson), 664
- Chromatography (Paper) 'Double Fronting' in, of Proteins (Hans G Boman), 703
  - A Handbook of, *review* by Dr. R. Consden, 50
  - Separation of the 2,4-Dinitrophenylhydrazones of Volatile Aldehydes and Ketones by (Dr. D. F Meigh), 579
  - Use of *n*-Butanol–Formic Acid–Water Mixture in the, of Amino-Acids and Sugars (Prof L. F. Wiggins and J. Howarth Williams), 279
- Chromatography of Amino-acids and Peptides in Filter Paper and other Media Salting out (L. Hagdahl and Prof. A. Tiselius), 799
- Chromatography of Rubber Accelerators and Anti-Oxidants on Silica Gel (Dr. C. A. Parker), 539
- Chromatography of Tissue Extracts containing Inorganic Iodide . A Possible Source of Artefacts in the (J D Acland), 32
- Chromium Oxide (Cr_2O_3) at the Antiferromagnetic Curie Temperature Anomalous Specific Heat of (Dr. J Volger), 1027
- Chromosome Numbers Basic, in the Genus *Cerastium* (Oliver E. Brett), 251
- Chromosomes of the Indian Water Buffalo (M. K. Dutt and P. Bhattacharya), 1129
- Chromosomes (Grasshopper) : Electron Microscope Study of (A. Guha, M. L De and S. P. Ray-Chaudhuri), 360
- Churchill Gold Medal of the Society of Engineers awarded to Sir Frank Whittle, 564
- Chymia, Annual Studies in the History of Chemistry, Vol. 3 (Henry M Leicester, editor-in-chief), *review*, 596
- Chymotrypsinogen Isoelectric Point of, by a Donnan Equilibrium Method (Vernon M. Ingram), 250
- Citrus (Florida) Molybdenum Deficiency in (Dr Ivan Stewart and C D. Leonard), 714
- Citrus Entomology in the Middle East (F. S Bodenheimer), *review* by Prof. H. C. Efflatoun, 218
- Citrus Fruit Production Entomology and, *review* by Prof. H C Efflatoun, 218
- Civil Defence The Place of the Scientist in (London and South-Eastern Counties Section of the Royal Institute of Chemistry, the Institute of Biology, and the London and Home Counties Branch of the Institute of Physics Discussion on), 406, 957
  - Regional Scientific Advisers for (Home Office appointments), 737
- Classical Methods in Chemical Analysis A Contemporary Assessment of the Place of (Prof van Nieuwenburg), 599
- Classification of the Fungi (Linnean Society Discussion on), 997
- Clathrate Compound (Oxygen) Preparation and Magnetic Susceptibility of an (D. F. Evans and Dr. R. E. Richards), 246
- Clay Minerals, *review* by Dr F. A. Bannister, 337
- Clay Minerals X-Ray Identification and Crystal Structures of (edited by G W. Brindley), *review* by Dr. F. A. Bannister, 337
- Clayey Deposits Natural Moisture-content, Porosity and Compaction of (Prof P. G. H. Boswell), 156
- Clayton Awards for 1952 of the Institution of Mechanical Engineers, 229
- Clear-Felling in Forestry The Alternative to Extensive Regular (M J Penistan), 607
- Climatology Air Mass, of the British Isles, 27
- Clinic and Society, *review* by Prof John Cohen, 592
- Clinker in Industry . Ash and (T. F. Hurley), 999
- Cloud Chamber : C. T R Wilson and the (S. Barron), 404
- Coal . Constitution of, and the Formation of Coke (Dr. W. A. Kirkby and Prof. R J. Sarjant), 597
  - Methane and (Sir Alfred Egerton), 93

  Nature of the Solution obtained by Pyridine Extraction of (E. Boult, H. R. Thirsk and H. E. Blayden), 317
Coal Chemicals : Coal, Coke and (Dr. Philip J. Wilson, Jr., and Dr. Joseph H. Wells), *review* by Dr. A. C. Monkhouse, 595
Coal Measures of Bacup, Lancashire : A Ligulate Pteridophyte from the Lower (Dr. H. Duerden and A. S. Wright), 41
Coal Science Lecture of the British Coal Utilization Research Association (Sir Alfred Egerton), 93
Coal, Coke and Coal Chemicals (Dr. Philip J. Wilson, Jr., and Dr. Joseph H. Wells), *review* by Dr. A. C. Monkhouse, 595
Coal-Tar Dyestuffs : Dyeing with (Dr. C. M. Whittaker and C. C. Wilcock), fifth edition, *review* by Dr. S. M. Neale, 52
Coal Tar Fraction : Isolation of 11 : 12-Benzfluoranthene from a (A. S. Harris), 461
Coals : Infra-Red Spectra of (R. R. Gordon, W. N. Adams and G. I. Jenkins), 317
Cobalt in the Nutrition of Ruminants—Response of Cobalt-deficient Sheep to Massive Doses of Vitamin B_{12} (Hedley R. Marston and H. John Lee), 791 ; Control of Cobalt-deficiency in Sheep by Injection of Vitamin B_{12} (Hedley R. Marston and Richard M. Smith), 792 ; Influence of Cobalt on the Production of Factors possessing Vitamin B_{12}-like Activity in the Faeces of Sheep (Mary C. Dawbarn, Denise C. Hine and Patricia Hughes), 793
Cobalt-deficient Lambs : Response to Vitamin B_{12} of Grazing (J. P. Anderson and E. D. Andrews), 807
Coccidiosis (Avian) : Lowered Liver Vitamin A Reserves in (Alan W. Davies), 849
Coccinia indica Wight and Arn. : Sex Mechanism in (L. S. S. Kumar and S. Vishveshwaraiah), 330
Coccoliths of *Coccolithus huxleyi* seen in an Electron Microscope (Prof. T. Braarud and E. Nordli), 361
Coccolithus huxleyi : Coccoliths of, seen in an Electron Microscope (Prof. T. Braarud and E. Nordli), 361
Cockroach Cuticle : A Lipoprotein Precursor of Sclerotin in the (S. R. A. Malek), 850
Coil (Coiled)? : Is α-Keratin a (F. H. C. Crick), 882
Coke : Constitution of Coal and the Formation of (Dr. W. A. Kirkby and Prof. R. J. Sarjant), 597
Coke and Coal Chemicals : Coal, (Dr. Philip J. Wilson, Jr., and Dr. Joseph H. Wells), *review* by Dr. A. C. Monkhouse, 595
Colchicine : Acquired Resistance to, in a Strain of *Trichomonas vaginalis* (Prof. S. Adler, A. Back and A. Sadovsky), 930
Collagen : The Reactivity of Protein Fibres—some Analogies between Keratin and (Prof. J. B. Speakman), 1054
Colleges : The Grant in aid of Universities and (Fifth Report from the Select Committee on Estimates), 171
Colombia : Cacao Collecting Expedition to (Imperial College of Tropical Agriculture and the Government of Colombia), 441
Colonial Agriculture : Statistics for (G. E. Hodnett), 26
Colonial Development : The Price of, 293
Colonial Development and Welfare—Details of Schemes for the Year 1951–52, 311
Colonial Plant and Animal Products, Vol. 2, No. 3, 405
Colonial Research and Development (Bernard Braine), 871
Colonial Territories, 1951–52 : British, 303
Colonial Territories (British) : Library Services in the (Lionel R. McColvin), 169
Colonization of Plant Debris by *Coprinus* Species in Soils (E. J. Chinnayya), 252
Colorimetric Determination of Formaldehyde under Mild Conditions (T. Nash), 976
Colour, in Theory and Practice (edited by H. D. Murray), new edition, revised, enlarged and re-written by R. Donaldson, V. J. Francis, P. Holliday, R. G. Horner, N. Laycock, L. C. Thomson, G. T. Winch and the editor, *review* by Dr. S. Clay, 859
Colour in Electron Microscopy (Dr. G. E. Donovan and E. Stafford), 1126
Colour Change in the Echinoid, *Diadema antillarum*, Philippi (Prof. N. Millott), 325
Colour Preferences : Objectivity of (Dr. G. W. Granger), 778
Colour Processes : Retinal, caused by Intermittent White Light (Prof. Koiti Motokawa and Mituru Ebe), 79
Colour Reagent : Ultra-Violet Papyrography—an Automatic Analytical Apparatus using Filter Paper without a (Dr. Yohei Hashimoto and Itsuhiko Mori), 1024
Colour Television (Colour Group of the Physical Society Discussion on), 1094
Colour Temperature Scale : The N.P.L., 783
Colour Vision (Defective) : New Studies on (Prof. W. D. Wright), 904
Colour-Blindness : Tests for (Prof. Shinobu Ishihara), tenth edition, *review* by Prof. W. D. Wright, 596
Columbium Oxide Bands : Rotational Analysis of the (S. Suryanarayana Rao), 670
Combustion : International Symposium on (Massachusetts Institute of Technology), 60
  Slow, of Cyclopropane (A. C. McEwan and Dr. C. F. H. Tipper), 462
Commonwealth, 1952 : The Yearbook of the Universities of the (published for the Association of Universities of the British Commonwealth), twenty-ninth issue, *review*, 133
Commonwealth (British) : Catalogue of an Exhibition illustrating the Medicine of the Aboriginal Peoples in the (Wellcome Historical Medical Museum), 273
Commonwealth Institute in London : A, 899
Communication in the Honeybee Colony : New Evidence of (C. R. Ribbands, Dr. H. Kalmus and H. L. Nixon), 438
Communication Theory : Applications of (Institution of Electrical Engineers Symposium on), 1051
Communist States : Science in, 1049
Compaction of Clayey Deposits : Natural Moisture-content, Porosity and (Prof. P. G. H. Boswell), 156
Competitive Action of Isonicotinic Acid Hydrazide and Vitamin B_6 in the Formation of Indole by *E. coli* (Masahiko Yoneda, Nobuo Kato and Mitsuharu Okajima), 803
Composition of the Bottom Fauna of the Dogger Bank Area : Change in the (Erik Ursin), 324
Compounds : Heterocyclic, *review*, 384
  Organophosphorus (Prof. Gennady M. Kosolapoff), *review* by J. Idris Jones, 637
  Six-Membered Heterocyclic Nitrogen, with Four Condensed Rings (C. F. H. Allen, in collaboration with D. M. Burness, Jean V. Crawford, F. W. Spangler, Eleanor R. Webster and C. V. Wilson), *review*, 384
Compounds (Carbon) : Chemistry of (edited by Dr. E. H. Rodd), Vol. 1, Part A, *review*, 508
Compounds (Carcinogenic Chemical) : Extension of the *K*-Region Hypothesis of (E. C. Kooyman and J. W. Heringa), 661
Compounds (Organic) : Chemistry of (Prof. Carl R. Noller), *review* by G. Fowles, 431
  Fluorescence of, *review* by Dr. E. J. Bowen, 296
  Identification of, from Infra-Red Spectra (Dr. A. E. Martin), 20
Compton Radiation from Solids : Spectrum of the (Kessar Alexopoulos and Gosta Brogren), 886
Computing Machine Terminology (Dr. Andrew D. Booth), 986
Computing Machines : Terminology applied to (Prof. Reginald O. Kapp), 547
Concrete : Mechanism of Fracture of (Dr. Frank A. Blakey), 1120
Conduct of Life : The (Lewis Mumford), *review* by R. Brightman, 1085
Conductance in Non-aqueous Solutions (R. C. Schonebaum), 422
Conducting Films of Gold : Transparent, 236
Conductivities in the Earth's Upper Atmosphere : Dynamo Currents and (Dr. S. F. Singer, E. Maple and W. A. Bowen, jun.), 1093
Conductivity of the Ionosphere (Dr. W. G. Baker and Dr. D. F. Martyn), 1090
Configuration of the Peptide Link and of Asparagine in Glycyl L-Asparagine (Dr. Lewis Katz, R. A. Pasternak and Prof. Robert B. Corey), 1066
Conlepicdulum gundrensis in *Calotes versicolor* Preserved in Formalin : Viability of (N. G. S. Raghavan), 125
Constitution of Alloys : Research on the (Constitution of Alloys Group of the British Iron and Steel Research Association), 305
Consultation : Joint, in British Industry (Report of an Inquiry undertaken by the National Institute of Industrial Psychology), 255
  Joint, in Management, 255
Consultation (Joint) : The Framework of (J. H. Smith and Miss R. J. Carey), 255
Contamination of Geiger–Muller Counters : Gaseous (D. Keefe, Dr. T. E. Nevin, Prof. C. B. A. McCusker and N. A. Porter), 501
Contrasting Methods of Transmission of Animal Viruses by Mosquitoes (Prof. Frank Fenner and Dr. M. F. Day), 204
Conversion of Wheat into Rye, Barley and Oats : Lysenko's Latest Discovery—The (Prof. P. Maheshwari), 66
Cooling Bath for Cytological Investigations (Dr. L. G. E. Bell), 719
Coopers Hill War Memorial Prize of the Institution of Civil Engineers awarded to Dr. E. J. Hamlin, 870
Copenhagen Biological Conference, 23
Copepods New to British Waters (R. V. Gotto), 674
Copley Medal of the Royal Society awarded to Prof. P. A. M. Dirac, 826, 946
Copolymerization (Turner Alfred, Jr., John J. Bohrer and H. Mark), *review* by Prof. H. W. Melville, 1089
Copper–Nickel Alloys : Lattice Vacancies and Porosity in (Dr. E. C. Ellwood), 580
Coprinus Species in Soils : Colonization of Plant Debris by (E. J. Chinnayya), 252
Copyright and the Scientist (Leslie Wilson), 1108
Corchorus capsularis : Origin and Development of Axillary Buds in Jute (Dr. B. C. Kundu and N. S. Rao), 1128
Corchorus capsularis, Linn. : Corchsularin, a New Bitter Principle from Jute Seeds (M. A. Khalique and M. Ahmed), 1019
Corchorus olitorius Linn. : *Nupserha bicolor* Thoms., subsp. *postbrunnea* Breun., a New Pest on Jute (N. Dutt), 287
Corchsularin, a New Bitter Principle from Jute Seeds (*Corchorus capsularis*, Linn.), (M. A. Khalique and M. Ahmed), 1019
Cores of Terrestrial Planets (Prof. K. E. Bullen), 363
Corona : A Diffraction, near the Centre of the Spiral Nebula NGC 4216 (Prof. Bertil Lindblad and Aina Elvius), *erratum*, 61
Corticium praticola Kotila, an Interesting Basidiomycete occurring in England (N. T. Flentje), 892
Corticoids (Antitumorigenic) : Structural Features of (Dr. Elvira Mardones, Dr. R. Iglesias, Dr. P. Fuenzalida, Dr. S. Bruzzone and Prof. A. Lipschutz), 917
Corticosteroids (Urinary) : Determination of (Dr. J. K. Norymberski), 1074
Cortisone : Effect of, on the Blood Pressure of Normal Rats (C. Bertazzoli, Prof. C. Cavallero and G. Sala), 43
  Sepsis and (Charles Cook and Charles Smith), 980
  Simple Analogues of (Dr. J. D. Billimoria), 248
Cortisone and Salicylate : Antagonistic Effects of (M. J. H. Smith), 240
Cosmetics and Dermatitis (Dr. E. J. Moynahan), 22
Cosmic Radiation (Low-Energy Primary) : Apparent Absence of (E. G. Dymond), 1078
Cosmic Rays : Meteorites and (Dr. S. F. Singer), 728 ; (Prof. F. A. Paneth), 729
Cosmic Rays and the Sun's Magnetic Field—Apparent Absence of Low-energy Cosmic-ray Primaries (S. F. Singer and J. A. Van Allen), 62 ; Diurnal Variation of Cosmic Rays and the Sun's Magnetic Field (S. F. Singer), 63
Cosmology (H. Bondi), *review* by Prof. W. H. McCrea, 768
Cotton in Peace and War : Protection of, *review*, 594
Counting with the Flying-Spot Microscope : High-Speed (F. Roberts and Prof. J. Z. Young), *erratum*, 19
Countings : Automatic Particle-Sizing by Successive (P. G. W. Hawksley), 984
Countries (Backward) : Development of, 677
Countries (Under-developed) : Problems of Land Reform in, 102
Coupling Azo Dye Methods for Histochemical Demonstration of Alkaline Phosphatase (Dr. E. Grogg and Dr. A. G. Everson Pearse), 578
Crampton Prize of the Institution of Civil Engineers awarded jointly to W. Storey Wilson and F. W. Sully, 870
Craterolophus tethys Clark in British Waters : The Stauromedusan (Dr. F. Segrove), 1023
Creams : The Assay of Adrenaline in (Dr. G. F. Somers), 236
Creatine Metabolism in Folic Acid Deficiency : A Sparing Effect of Formate or Methanol on the Impairment of (Prema Fatterpaker, Urmila Marfatia and Dr. A. Sreenivasan), 894
Creatinine : Determination of (R. J. Garner), 460
Cress Roots : Sensitivity of, to Indole-Acetic Acid (Dr. Franz Moewus and Liselotte Moewus), 372
Crooked-Toe Problem in Chicks : 'Infra-Red' Brooding and the (Dr. D. J. G. Black, J. Getty and T. R. Morris), 167

Cropping and Livestock Problems under Irish Conditions: Molybdenum in relation to (Dr. T. Walsh, M. Neenan and Dr. L. B. O'Moore), 149
Cross (Dorothy Temple) Research Travelling Fellowships in Tuberculosis (Medical Research Council Awards), 189
Cross-polarization of the Radar Melting-Band (Ian C. Browne and N. P. Robinson), 1078
Crossing-over: Four strand (Dr. A. R. G. Owen), 985; (Dr. T. C. Carter and Dr. Alan Robertson), 986
Crossing-over (Multiple Mitotic): Non-random Distribution of, among Nuclei of Heterozygous Diploid *Aspergillus* (Dr. G. Pontecorvo), 204
Crowd Behaviour: On the Objective Study of (Dr. L. S. Penrose), *review* by Prof. John Cohen, 472
Crystal Anisotropy: A New Method of Melting Ferromagnetic Semi-conductors—$BaFe_{12}O_{19}$, a New Kind of Ferromagnetic Crystal with High (H. P. J. Wijn), 707
Crystal Densities (Protein): Determination of (Dr. Barbara W. Low and Frederic M. Richards), 412
Crystal Distortion of Graphite in Cast Irons (Eitaro Matuyama), 1123
Crystal Habit as illustrated by Apatite: Growth Spirals and their Relation to (S. Amelinckx), 760
Crystal Structure of $BaFe_{18}O_{27}$ (Dr. P. B. Braun), 708
Crystal Structures of Clay Minerals: X-Ray Identification and (edited by G. W. Brindley), *review* by Dr. F. A. Bannister, 337
Crystalline Precipitates: Ageing of (Prof. I. M. Kolthoff), 599
Crystals containing the Plakalbumin-forming Enzyme from *Bacillus subtilis*: Preparation of (A. V. Guntelberg and M. Ottesen), 802
Crystals of Tungsten Trioxide: Twinning Structure in (R. G. Rhodes), 369
Ctenamphiura Verrill: Rediscovery of the Ophiuroid Genus (Dr. H. Barraclough Fell), 327
Cuckoos: Fleas, Flukes and (Miriam Rothschild and Theresa Clay), *review* by Dr. E. Hindle, 382
Culture (Pure): Growth Factor Requirements of *Pellicularia koleroga* Cooke in (K. T. Mathew), 889
Culture Contact: A Study in, *review* by D'Arcy Ryan, 551
Curie Temperature (Antiferromagnetic): Anomalous Specific Heat of Chromium Oxide (Cr_2O_3) at the (Dr. J. Volger), 1027
Current (High Constant-voltage): Paper Electromigration of Flavonoids and Sugars using a (Dr. Yohei Hashimoto, Itsuhiko Mori and Mutsuo Kimura), 975
Current Affairs: Electricity and (Colonel H. B. Leeson), 874
Curvature: Evaluation of Small Radii of, using the Light-Profile Microscope (Prof. S. Tolansky and M. Omar), 758
Cuticle (Cockroach): A Lipoprotein Precursor of Sclerotin in the (S. R. A. Malek), 850
Cycas revoluta Thunb.: Abnormal Leaves of (Ramesh Kumar Srivastava), 253
Cyclopropane: Slow Combustion of (A. C. McEwan and Dr. C. F. H. Tipper), 462
Cyclotron: The Oak Ridge 86-in. (Dr. Robert S. Livingston), 221
Cyclotron (Large-) Research at the University of Chicago (Prof. E. Fermi), 612
Cyprus: Archaeology in, 1951 (A. H. S. Megaw), 269
Cysteic Acid Transaminase (Sven Darling), 749
Cytochemical Localization of Esterases using Indoxyl Derivatives (Dr. S. J. Holt and R. F. J. Withers), 1012
Cytochemical and Cytological Studies of Drug Action (Prof. J. F. Danielli), 863
Cytochrome *c*: Purification of (Dr. E. Margoliash), 1014
Cytochrome Components in Chloroplasts (H. E. Davenport), 1112
Cytological Investigations: Cooling Bath for (Dr. L. G. E. Bell), 719
Cytological Studies of Drug Action: Cytochemical and (Prof. J. F. Danielli), 863
Cytology: Recent Advances in (British Association for the Advancement of Science, Section D (Zoology), Discussion on), 655
Cytoplasmic Actions of Drugs: Separate Nuclear and (Prof. J. F. Danielli), 1042
Cytoplasmic Polyhedral Virus Diseases (N. Xeros), 1073

DACRYDIUM: Chemical Differentiation of the Genera *Podocarpus* and (the late C. W. Brandt and B. R. Thomas), 1018
Daly Medal of the American Geographical Society presented to J. M. Wordie, 961
'Daraprim': A New Anti-malarial Drug (Burroughs Wellcome and Co.), 17
'Daraprim' Resistance in Experimental Malarial Infections (L. M. Rollo), 415
Darkroom Lights: Coloured 'Perspex' for (L. A. T. Ballard), 840
Dart Poison used in Malaya: Pharmacological and Toxicological Actions of (Robert Chun Yu Lin), 416
Darwin Medal of the Royal Society awarded to Prof. J. B. S. Haldane, 826, 947
Dating the Libyan Desert Silica-Glass (Dr. Kenneth P. Oakley), 447
Davy Medal of the Royal Society awarded to Prof. Alexander Robertson, 826, 947
D—D Reaction: Evidence for the Polarization of the Protons produced in the (G. R. Bishop, G. Preston, J. M. Westhead and H. H. Halban), 113
DDT: Inactivation of, by Soils (A. B. Hadaway and F. Barlow), 762
DDT, BHC and Dieldrin: Experiments on the Use of, against Adult Mosquitoes at Taveta, Kenya (G. Davidson), 702
DDT-Dehydrochlorination: Phosphorus as a Factor Preventing (H. Mies), 328
de Haas–van Alphen Effect at High Fields (Dr. D. Shoenberg), 569
Deaf: Education of the (British Association for the Advancement of Science, Section L (Education), Discussion on), 525
  Education of the (Sir Richard Paget), 672
Death: Origin of, Studies in African Mythology (Hans Abrahamsson), *review* by G. I. Jones, 993
Decay of Light to Very Low Levels from Spark Discharges (R. H. Johnson and D. E. H. Jones), 669
Decay Schemes of Silver-110, Antimony-124 and Iodine-131: Scintillation Spectrometer Studies on the (S. Almqvist and Sven A. E. Johansson), 583
Decomposition: Thermal, of Normal Paraffins (Clifford G. Silcocks and Prof. Morris W. Travers), 1028; (Sir Cyril Hinshelwood and C. J. Danby), 1029
Decomposition (Homolytic): Thiol Catalysis of the, of Aldehydes (Dr. E. F. P. Harris and Dr. W. A. Waters), 212
Decomposition: Microbial, of Cellulose (R. G. H. Siu), *review*, 594
Decomposition (Thermal): Inhibition of the, of Diethyl Peroxide (A. D. Jenkins and Dr. W. G. Style), 706
Decomposition of Organic Matter by Recoil Atoms from an Adjacent Phase (D. F. Sangster and J. Wright), 368
Deformation Textures of Titanium: Origin of the (D. N. Williams and Prof. D. S. Eppelsheimer), 146
Degradation: Enzymic, of Pectic Acid and the Complex Nature of Polygalacturonase (Audrey Ayres, J. Dingle, A. Phipps, W. W. Reid and G. L. Solomons), 834
  Oxidative, of Testosterone by Adaptive Enzymes (Dr. Paul Talalay, Marie Mollomo Dobson and Donald F. Tapley), 620
  Stepwise, of the Peptides liberated in the Transformation of Ovalbumin to Plakalbumin (Martin Ottesen and Albert Wollenberger), 801
Dehydrochlorination, DDT-: Phosphorus as a Factor Preventing (H. Maes), 328
Delinquency: The Earliest Stages of (H. Edelston), *review* by Dr. Clifford Allen, 595
Δ-E Effect in Nickel: Magnetostrictive Effect and the (Henrik Nordvedt), 884
Denaturation (Protein): Behaviour of a Synthetic Polypeptide analogous to (Dr. A. Elliott), 1066
Denmark: The Campaign against Bovine Tuberculosis in, and its Eradication (T. Mathiesen), 102
  Sub-Fossil Hekla Pumice from (Prof. A. Noe-Nygaard), 227
4-Deoxy-L-Ribose (P. F. V. Ward and Dr. P. W. Kent), 936
Deoxyribonucleic Acid: Physical Chemistry of (Dr. B. E. Conway), 691
Deoxyribonucleic Acid Content of Haploid and Diploid *Aspergillus* Conidia (Dr. F. C. Heagy and Dr. J. A. Roper), 713
Deoxyribonucleic Acids: Polynucleotides from (Dr. J. D. Smith and Dr. Roy Markham), 120
Deoxyribose in Animal Tissues: Synthesis of (Mary G. McGeown and Dr. F. H. Malpress), 575
Deposition of Metal Films on Jelly-like Materials (Edwin Rosenstiel), 85
Depressant Properties of Barbiturates: Autonomic Ganglion (K. A. Exley), 242
Dermatitis: Cosmetics and (Dr. E. J. Moynahan), 22
Des Voeux Memorial Lecture of the National Smoke Abatement Society (W. R. Hornby Steer), 484
Désert de Judée: Le paléolithique et le mésolithique du (René Neuville), *review* by M. C. Burkitt, 386
Desert Research: International Symposium on (Research Council of Israel in co-operation with Unesco), 300
Deserts (Hot and Cold): Biology and Productivity of (Institute of Biology Symposium on), 951
Desiccation: Effect of, on the Humidity Response of *Tenebrio* (S. E. Dodds and Dr. D. W. Ewer), 758
Design and Analysis of Experiments (Prof. Oscar Kempthorne), *review* by Dr. D. J. Finney, 991
Designers for the Printing Industry: Training of (London and Home Counties Regional Advisory Council), 18
'Detectivity', the Reciprocal of Noise Equivalent Input of Radiation (R. Clark Jones), 937
Detoxication of Hormone Herbicides by Soil Bacteria (Dr. H. L. Jensen and H. Ingv. Petersen), 39
Development of the Avian Pituitary from a Comparative and Functional Viewpoint: The Structure and (Karl Georg Wingstrand), *review* by Dr. A. J. Marshall, 553
Development of Backward Countries, 677
Development in the British Industry: Research and, a Survey of Expenditure on Industrial Research and Development in the Year 1950–51 (Industrial Research Committee of the Federation of British Industries), 465
Developmental Work: Principles Governing the Amount of Experimentation in (Dr. F. Yates), 138
Deviations (Standard): Rapid Estimation of (Dr. B. Woolf), 631
Devon and Cornwall Exhibition in Pharmacy of the Pharmaceutical Society awarded to A. James, 346
Dextran in Rats: Toxicity of (T. Edlund, B. Lofgren and L. Vali), 125
Dextran in the Tissues of Rabbits: Distribution of (Bengt H. Persson), 716
Diadema antillarum, Philippi: Colour Change in the Echinoid (Prof. N. Millott), 325
Diameter: Effect of Variation in, on the Torsional Vibration of Bars (H. Pursey), 502
Diapensia lapponica in Scotland (J. Grant Roger), 783
Diazo Reaction of Urine in Severe Tuberculosis: Relation of 3-Hydroxykynurenine to the Ehrlich (Dr. Katashi Makino, Kiyoo Satoh, Tetsuo Fujiki and Kazuo Kawaguchi), 977
Dichlorophenoxyacetic Acid: Phytotoxicity of Histamine, Arsenic Acid and, and Methods of Testing (C. G. Greenham), 535
2 : 4 Dichlorophenoxyacetic Acid: Effects of Preliminary Treatment on the Subsequent Variation in the Resistance of *Lemna minor* to the Phytotoxic Action of (R. C. Robertson-Cuninghame and Prof. G. E. Blackman), 459
Dichloropropene-Dichloropropane Soil Fumigant: Tainting of Tobacco by a (C. J. Shepherd), 1073
Dichroism of Tobacco Mosaic Virus Nucleoprotein: Infra-Red (Dr. R. D. B. Fraser), 491
Dichroism and Protein Structure: Infra-Red (Dr. R. D. B. Fraser and Dr. W. C. Price), 490
Dichromate and Diphenylcarbazide: Mechanism of the Reaction between (Monisha Bose), 213
Dictionary of Breeds, Types and Varieties of Livestock: A World (I. L. Mason), *review* by Dr. John Hammond, 260
Dieldrin: Experiments on the Use of DDT, BHC and, against Adult Mosquitoes at Taveta, Kenya (G. Davidson), 702
Dielectric Breakdown of Solids (S. Whitehead), *review*, 219
Dielectric Constant of Water Films (Prof. L. S. Palmer, Dr. A. Cunliffe and J. M. Hough), 796
Dielectric Material: A New (Dr. L. Nicolini), 938
Dielectric Multiple Films in Interferometry: Silver Films and (Dr. D. A. Jackson and K. Kuhn), 455; (Dr. A. H. Jarrett), 456
Dielectric Observations of Nucleation (Dr. Vera Daniel and Mrs. Clara Turner), 1122
Diet: Effect of the Percentage of Dry Matter in the, on the Dry-Matter Intake in Ruminants (T. L. Dodsworth and W. H. McK. Campbell), 1128

Diethyl Peroxide : Inhibition of the Thermal Decomposition of (A. D. Jenkins and Dr. D. W. G. Style), 706
Diethyl Peroxide and Nitric Oxide : Reaction between (H. N. Mortlock and Dr. D. W. G. Style), 706
Difficulty Relationships within a Problem-solving Situation Some Speed, Error and (W. D. Furneaux), 37, *erratum*, 269
Diffraction (Electron) The Born Approximation in (Prof. Verner Schomaker and Dr. Roy Glauber), 290
Diffraction Corona near the Centre of the Spiral Nebula NGC 4216 (Prof. Bertil Lindblad and Aina Elvius), *erratum*, 61
Diffraction Maxima (Small-angle X-Ray) Occurrence of, in some Artificial Cellulose Fibres (D. Heikens, P. H. Hermans and A. Weidinger), 369
Diffraction Microscopy with X-Rays (M. E. Haine and T. Mulvey), 202
Diffusion Analysis by, *review* by A. L. Bacharach, 5
Diffusion Reaction Theory of Morphogenesis, 955
Digestive Tract : Glucuronide Decomposition in the (C. A. Marsh, F. Alexander and Dr. G. A. Levvy), 163
Digitalis Glycosides on Paper Chromatograms . Detection of (Dorothy Lawday), 415
Dilutions (High) : Electrometric Determination of Ozone at (Dr. J. N. Pring and G. M. Westrip), 530
2,4-Dinitrophenylhydrazones of Volatile Aldehydes and Ketones Separation of the, by Paper Chromatography (Dr. D. F. Meigh), 579
Diphenylcarbazide Mechanism of the Reaction between Dichromate and (Monisha Bose), 213
Diphosphopyridine Nucleotide : Synthesis of, by Cell Nuclei isolated in Aqueous Media (Dr. George H. Hogeboom and Dr. Walter C. Schneider), 374
Diploid *Aspergillus* (Heterozygous) : Non-random Distribution of Multiple Mitotic Crossing-over among Nuclei of (Dr. G. Pontecorvo), 204
Diploid *Aspergillus* Conidia Deoxyribonucleic Acid Content of Haploid and (Dr. P. C. Heagy and Dr. J. A. Roper), 713
Dirac's New Electrodynamics: Angular Momentum in (R. W. Iskraut), 1125
Dirac's New Electromagnetic Theory . The Energy Momentum Tensor in (Prof. Banesh Hoffmann), 1126
Disabled Youth in Glasgow : Employment Problems of (Medical Research Council Committee on the Resettlement of the Disabled Memorandum on), 833
Discharges (Spark) : Decay of Light to Very Low Levels from (R. H. Johnson and D. E. H. Jones), 669
Discovery II, R.R.S. : Geophysical Research aboard the, 17
Discrete Radio Sources : Apparent Angular Sizes of—Observations at Jodrell Bank, Manchester (R. Hanbury Brown, R. C. Jennison and M. K. Das Gupta), 1061 ; Observations at Sydney (B. Y. Mills), 1063 ; Observations at Cambridge (F. G. Smith), 1065
Dislocations on Electrolytically produced Titanium Crystals : Growth Spirals originating from Screw (M. A. Steinberg), 1119
Dislocations in Pyrite : Screw (A. F. Seager), 425
Dislocations in Quartz . Screw (B. T. M. Willis), 115
Dispersal : Airborne, of *Phytophthora palmivora*, causing Black-Pod Disease of *Theobroma cacao* (C. A. Thorold), 718
Dispersal of Juvenile Titmice : The Post-fledging (Ivan M. Goodbody), 1002
Distillation (Extractive) : Vapour-Liquid Equilibrium Relations in (Dr. E. F. G. Herington), 935
Distribution of the Intertidal Barnacles in relation to the Environment : Changes in the (A. J. Southward and D. J. Crisp), 416
Diurnal Variations in the Blood Picture of Cattle (R. N. T.-W.-Fiennes), 934
Division of the Flattened Egg (Prof. J. F. Danielli), 496
Dog (Water-loaded) : Adrenaline Antidiuresis in the (O. Eränkö and M. J. Karvonen), 331
Dogger Bank Area : Change in the Composition of the Bottom Fauna of the (Erik Ursin), 324
Dolichos biflorus : Relationship of the Blood Sub-Groups A_1, A_2 and A_1B, A_2B to Hæmagglutinins present in the Seeds of (Lieut.-Colonel G. W. G. Bird), 674
Domestic Electrical Installations—Some Safety Aspects (H. W. Swann), 18
Domestic Heating : The Science of (J. S. Hales), 302
Dominions (Overseas) : Aspects of Settlement in the (Prof. R. O. Buchanan), 395
Donnan Equilibrium Method : Isoelectric Point of Chymotrypsinogen by a (Vernon M. Ingram), 250
'Double Bang' of Supersonic Aircraft (T. Gold), 808
'Double Fronting' in Paper Chromatography of Proteins (Hans G. Boman), 703
Dow Latex '580G' : Resuspension of, by Ultrasonics (P. Hatfield, H. W. Emerton and P. E. Wrist), 797
Drilling and Soil-Temperature Measurements : Permafrost, at Resolute, Cornwallis Island, Canada (Andrew Thomson and P. C. Bremner), 705
Drosera capensis L. : Transport of Substances through the Tentacles of Leaves of (Prof. W. H. Arisz), 932
Drug Action . Cytochemical and Cytological Studies of (Prof. J. F. Danielli), 863
Drugs : Separate Nuclear and Cytoplasmic Actions of (Prof. J. F. Danielli), 1042
Drugs (Vegetable) : Ash Pictures in the Identification and Assay of (Prof. Gosta Edman), 954
Dry Matter in the Diet : Effect of the Percentage of, on the Dry-Matter Intake in Ruminants (T. L. Dodsworth and W. H. McK. Campbell), 1128
Dry-Matter Intake in Ruminants . Effect of the Percentage of Dry Matter in the Diet on the (T. L. Dodsworth and W. H. McK. Campbell), 1128
Drying : Effect of, upon the Absorption Spectra of Hæmoglobin and its Derivatives (Prof. D. Keilin and Dr. E. F. Hartree), 161
  Freezing and—Report of a Symposium held in June 1951 (Institute of Biology), *review* by Dr. Geoffrey H. Bourne, 723
Drying Tissues . Edmond About and the Technique of Freezing and (L. G. E. Bell), 547 ; (R. Legendre), 1080
Ductless Glands . Functions of the—Fiftieth Anniversary, 871
Duddell Premium of the Institution of Electrical Engineers awarded to Dr. K. Weekes, 19
Dusky-footed Wood Rat (Jean M. Linsdale and Lloyd P. Tevis, Jr.), *review* by Dr. L. Harrison Matthews, 471
Dyeing with Coal-Tar Dyestuffs (Dr. C. M. Whittaker and C. C. Wilcock), fifth edition, *review* by Dr. S. M. Neale, 52
Dyeing and Printing : The Chemical Technology of (Dr. Louis Diserens), Vol. 2, translated and revised from the second German edition by Paul Wengraf and Herman P. Baumann, *review* by Dr. S. M. Neale, 178
Dyestuffs (Coal-Tar) : Dyeing with (Dr. C. M. Whittaker and C. C. Wilcock), fifth edition, *review* by Dr. S. M. Neale, 52
Dynamic Conditions : Work-hardening of Annealed Mild Steel under Static and (A. W. Crook), 1124
Dynamics (Molecular) : Molecular Spectra and, *review* by Dr. H. W. Thompson, 469
Dynamics of Insect Flight Flight-Tone and Wing-Stroke Frequency of Insects and the (Dr. Olavi Sotavalta), 1057
Dynamo Currents and Conductivities in the Earth's Upper Atmosphere (Dr. S. F. Singer, E. Maple and W. A. Bowen, jun.), 1093
Dytiscus and *Locusta* Abdominal Mechano-Receptors in (G. M. Hughes), 531

E-REGION during the Solar Eclipse of February 25, 1952 (C. M. Minnis), 453
Early-Morning Ionospheric Phenomenon : A New (B. N. Bhargava), 983
Earth : Sectioned Model of the, in Manchester Museum, 523
  Temperature of the Interior of the (Prof. J. A. Jacobs), 838
Earth's Inner Core Detection of *S* Waves in the (Prof. K. E. Bullen and the Rev. T. N. Burke-Gaffney), 435
Earth's Mantle : Wave Velocities in the Outer Part of the (Prof. B. Gutenberg), 289
Earth's Upper Atmosphere : Dynamo Currents and Conductivities in the (Dr. S. F. Singer, E. Maple and W. A. Bowen, jun.), 1093
Earthquake near Kamchatka, 914
Earwig (Common), *Forficula auricularia* : Seasonal Change in the Humidity Reaction of the (Dr. Vilho Perttunen), 209
East Africa Groundnuts Scheme in, 782
  Makerere College—The University College of, 25
East and Central Africa Education of Africans in (A. L. Binns), 399
Echinoid, *Diadema antillarum*, Philippi . Colour Change in the (Prof. N. Millott), 325
Echo Sounder Studies Recent (G. C. Trout, A. J. Lee, I. D. Richardson and F. R. Harden Jones), 71
Echoes Weak, from the Ionosphere with Radio Waves of Frequency 1·42 Mc./s. (S. Gnanalingam and K. Weekes), 113
Eclipse of the Sun (Two articles in *L'Astronomie*), 914
Ecology : Research Studentships in (Nature Conservancy Awards for 1952), 524
Ecology of *Quercus sessiliflora* (*Q. petraea*), (P. Dineur), 652
Ecuador (South-west) : The Archæology of the Santa Elena Peninsula in (G. H. S. Bushnell), *review* by Miss B. M. Blackwood, 51
Education . Agricultural (Minister of Agriculture and Fisheries Working Party on), 1049
  Conception of Science in, 228
  The Film in (Dr. Andrew Buchanan), *review*, 387
  Higher, in Central Africa, 1001
  Higher Technological, 87
  Museums and (Unesco Seminar on), 307
  Reporting Research in (Stephen Wiseman), 607
  Scientific, of Physicists (Institute of Physics), 196
  Technical, in the North of England, 1099
  Technical and Technological, in Britain, 765
  Technological, in Manchester, 651
Education of Africans in East and Central Africa (A. L. Binns), 399
Education of the Deaf (British Association for the Advancement of Science, Section L (Education), Discussion on), 525 ; (Sir Richard Paget), 672
Education for a Pharmacist (H. B. Mackie), 787
Education and Training in Chemical Engineering (British Association for the Advancement of Science, Section G (Engineering), Discussion on), 644
Education and Training of Metallurgists (Prof. F. C. Thompson), 182
Education and Training of Metallurgists, 989
Egg in Mammals Passage of the Sperm and the Penetration of the (C. R. Austin and A. W. H. Braden), 919
Egg (Flattened) : Division of the (Prof. J. F. Danielli), 496
Egg (Hen's) Electrical Resistance and Structure of the (D. M. Maurice), 495
  Permeability of Yolk of the, to Bromine-82 (D. M. Maurice and A. Fidanza), 546
Egg-laying under Water of the Aerial Insect *Hydropsyche angustipennis* (Curtis) (Trichoptera) Observation of (Ruth M. Badcock), 40
Ehrlich Diazo Reaction of Urine in Severe Tuberculosis Relation of 3-Hydroxykynurenine to the (Dr. Katashi Makino, Kiyoo Satoh, Tatsuo Fujiki and Kazuo Kawaguchi), 977
Elasmobranch, *Scyllium canicula* (Marine) Presence of Ferritin in a (Dr. Giorgio Tecce), 75
Elastic Properties of Metals : Measurement and Importance of (Conference at the National Physical Laboratory, Teddington), 527
Elastic Tissue Structure of (Dr. D. A. Hall, Dr. R. Reed and Prof. R. E. Tunbridge), 264
Electrical Breakdown of Solids, *review*, 219
Electrical Conductivity of Cæsium Chloride near the Thermal Transition (W. W. Harpur and Prof. A. R. Ubbelohde), 975
Electrical Differences between Healthy and Virus-infected Potato Tubers : Some (C. G. Greenham, D. O. Norris, R. D. Brock and A. M. Thompson), *erratum*, 308
Electrical Discharges in Gases (British Association for the Advancement of Science, Section A (Mathematics and Physics), Discussion on), 601
Electrical Engineering in Britain, 874
Electrical Engineering in the Manchester College of Technology, 185
Electrical Engineering Abstracts, Vol. 54, 1951, *review* by S. Weintroub, 338
Electrical Engineers Abstracting for Physicists and, *review* by S. Weintroub, 338
Electrical Equipment . Vacation School on the Insulation of (Imperial College of Science and Technology), 1006, 1100
Electrical Installations Domestic—Some Safety Aspects (H. W. Swann), 18
Electrical Resistance and Structure of the Hen's Egg (D. M. Maurice), 495
Electricity and Current Affairs (Colonel H. B. Leeson), 874
Electroacoustics : International Congress on (International Commission on Acoustics of the International Union of Pure and Applied Physics), 1100
Electrochemical Processes : Thermodynamics of Irreversible (Peter H. Kemp), 1028
Electrodynamics (Dirac's New) Angular Momentum in (R. W. Iskraut), 1125

Electrolytically produced Titanium Crystals : Growth Spirals originating from Screw Dislocations on (M. A. Steinberg), 1119
Electromagnetic Momentum and Newton's Third Law (Prof. E. G. Cullwick), 425
Electromagnetic Theory (Dirac's New) : The Energy Momentum Tensor in (S. F. B. Tyabji), 116 ; (Prof. Banesh Hoffmann), 1126
Electrometric Determination of Ozone at High Dilutions (Dr. J. N. Pring and G. M. Westrip), 530
Electromigration : Paper, of Flavonoids and Sugars using a High Constant-voltage Current (Dr. Yohei Hashimoto, Itsuhiko Mori and Mutsuo Kimura), 975
Electron Diffraction : The Born Approximation in (Prof. Verner Schomaker and Dr. Roy Glauber), 290
Electron Microscope : Coccoliths of *Coccolithus huxleyi* seen in an (Prof. T. Braarud and E. Nordli), 361
Electron Microscope Studies on Thin Sections of Human Erythrocytes (W. Bernhard), 359
Electron Microscope Study of Grasshopper Chromosomes (A. Guha, M. L. De and S. P. Ray-Chaudhuri), 360
Electron Microscopy : Colour in (Dr. G. E. Donovan and E. Stafford), 1126
  Thin Glass Layers as Supports for (Prof. A. Van Itterbeek, L. De Greve, G. F. Van Veelen and C. A. F. Tuynman), 795
Electron Microscopy of Solid Surfaces (Electron Microscopy Group of the Institute of Physics Discussion on), 861
Electronic Instrumentation (French) : Progress in, 441
Electronic Instruments in Research and Industry : British (Scientific Instrument Manufacturers' Association of Great Britain Symposium on), 877
Electronic Instruments and Equipment (North-Western Branch of the Institution of Electronics Annual Exhibition), 407
Electronic Measurements Prize of the British Institution of Radio Engineers awarded to G. R. Barwick, 308
Electronic Orbitals, Shapes and Spectra of Polyatomic Molecules (Dr. A. D. Walsh), 974
Electronic and Ionic Impact Phenomena (Prof. H. S. W. Massey and E. H. S. Burhop), *review* by Prof. H. W. B. Skinner, 901
Electrons (High-energy) : An After-effect in Butter-fat Irradiated with (R. S. Hanna and H. J. Shepherd), 1021
Electro-osmosis : Streaming Potential and—A Model for the Mechanism of Streaming Potential (Dr. Horace E. Rose and G. Moss), 836 ; Mechanism of Electro-osmosis (K. L. Nash and N. W. Lister), 837
Electrophoresis of Serum Proteins : Paper (B. Levin and V. G. Oberholzer), 123
Electrophoresis Apparatus : A Simple Paper (Dr. R. Consden and Winifred M. Stanier), 1069
Electrophoresis Cell : An Improved, for the Analyses of Several Sera Simultaneously (Dr. A. Polson), 628
Elements : The Abundance of the (National Science Foundation, Washington, in co-operation with the University of Chicago, Conference on), 695
Elution Series : Ion-Exchange (Dr. R. C. Vickery), 665
Embryology and Evolution, *review* by Prof. S. Zuckerman, 5
Embryonic Coverings in the Scorpion, *Buthus quinquestriatus* (H.E.) : Development of the (Dr. A. Abdel-Wahab), 209
Embryos and Ancestors (G. R. de Beer), revised edition, *review* by Prof. S. Zuckerman, 5
Empire Mining and Metallurgical Congress : Fifth, 563
Employment : Full, in Retrospect (Prof. D. T. Jack), 396
Employment Problems of Disabled Youth in Glasgow (Medical Research Council Committee on the Resettlement of the Disabled Memorandum on), 833
Emulsin (Almond) : Synthetic Action of (Prof. Stanley Peat, Dr. W. J. Whelan and Mrs. K. A. Hinson), 1056
Emulsion Technique of Autoradiography : Improvements to the Melted (Prof. Leonard F. Bélanger), 625
Emulsions and Films (British Society of Rheology Symposium on), 232
Energetics of Sensory Effects (Dr. J. A. B. Gray), 823
Energy into Nerve Impulses (British Association for the Advancement of Science, Section I (Physiology), Discussion on), 823
Energy in the Service of Man (Unesco Discussion on), 611
Energy Momentum Tensor in Dirac's New Electromagnetic Theory (S. F. B. Tyabji), 116 ; (Prof. Banesh Hoffmann), 1126
Engineering Research Fellowships (British Thomson-Houston Co., Ltd.), 59
Engineering, Biophysics and Physics at King's College, London—New Building (Dr. M. H. F. Wilkins), 261
England : *Corticium praticola* Kotila, an Interesting Basidiomycete occurring in (N. T. Flentje), 892
England (North of) : Technical Education in the, 1099
English : The Use of (edited by Denys Thompson), Summer Number, 228
Enteramine-related Substances : Biological Activity of some (Dr. V. Erspamer), 281
Entomologist, The : N. D. Riley to relinquish the editorship of, 695
  Appointment of D. Leston as editor of, 695
Entomology and Citrus Fruit Production, *review* by Prof. H. C. Efflatoun, 218
Environment : Changes in the Distribution of the Intertidal Barnacles in relation to the (A. J. Southward and D. J. Crisp), 416
Environmental Temperature and the Glycogen Content of the Frog's Liver (*Rana temporaria*), (Dr. C. L. Smith), 74
Environmental Variation and Heterosis : Heterozygosity, (Dr. Forbes W. Robertson and Dr. E. C. R. Reeve), 286
Enzyme Systems : Enzymes and (edited by John T. Edsall), *review* by Dr. J. A. V. Butler, 134
Enzymes : The, Chemistry and Mechanism of Action (edited by James B. Sumner and Karl Myrbäck), Vol. 1, Parts 1 and 2, Vol. 2, Parts 1 and 2, *review* by A. L. Bacharach, 257
Enzymes for Building Natural and Synthetic Starch (Dr. G. A. Gilbert), 691
Enzymes of *Vibrio cholerae* (E. K. Narayanan and P. S. Menon), 621
Enzymes (Adaptive) : Oxidative Degradation of Testosterone by (Dr. Paul Talalay, Marie Mollomo Dobson and Donald F. Tapley), 620
Enzymes and Enzyme Systems (edited by John T. Edsall), *review* by Dr. J. A. V. Butler, 134
Enzymic Degradation of Pectic Acid and the Complex Nature of the Polygalacturonase (Audrey Ayres, J. Dingle, A. Phipps, W. W. Reid and G. L. Solomons), 834
Enzymic Splitting and Synthesis of Glutathione (P. J. Fodor, A. Miller and Dr. H. Waelsch), 841
Ephedrales : New Light on Gnetales and (Prof. A. J. Eames), 1099
Epidemiology : Mental, *review* by Prof. John Cohen, 472
Epidermal Glands in Centipedes (Gordon Blower), 166
Epididymis : 'Lipochondria' and the Golgi Substance in Epithelial Cells of the (A. J. Dalton and Marie D. Felix), 541
Epithelial Cells of the Epididymis : 'Lipochondria' and the Golgi Substance in (A. J. Dalton and Marie D. Felix), 541
Equilibria : A Genetical System admitting of Two Stable (Dr. A. R. G. Owen), 1127
Equilibria (Phase) : Principles of (F. E. W. Wetmore and D. J. LeRoy), *review* by Prof. J. R. Partington, 859
Equilibrium (Heterogeneous) : The Phase Rule and (Prof. John E. Ricci), *review* by Prof. J. R. Partington, 859
Ernährung : Landwirtschaftliche Zwischennutzung im Walde als Meliorationsmittel und Hilfe für die (W. Wittich), 562
Error and Difficulty Relationships within a Problem-solving Situation : Some Speed, (W. D. Furneaux), 37, *erratum*, 269
Error Function : Tables of the, and of its First Twenty Derivatives (Staff of the Computation Laboratory of Harvard University), *review* by Prof. W. G. Bickley, 1089
Erythermal Processes caused by Ultra-Violet Light in Human Skin : Localization of (P. B. Rottier and J. A. M. Mullink), 574
Erythrocyte Antigen *A* (Bovine) : Correlation Study of, and Butterfat Test (T. J. McClure), 327
Erythrocytes (Human) : Electron Microscope Studies on Thin Sections of (W. Bernhard), 359
E. coli : Competitive Action of Isonicotinic Acid Hydrazide and Vitamin B_6 in the Formation of Indole by (Masahiko Yoneda, Nobuo Kato and Mitsuharu Okajima), 803
  Inhibition of Lysine Decarboxylase from, by Homologous Rabbit Antibody (Arthur P. Howe and Prof. Henry P. Treffers), 123
Essay Competition (*Research*), 1049
Estate Forestry (Sir William Ling Taylor), *review* by N. D. G. James, 471
Estate Woodlands : A Prospect for, *review* by N. D. G. James, 471
Esterase : Acetylcholine, of the White Components of Blood (Mrs. B. E. Hines), 78
Esterases : Cytochemical Localization of, using Indoxyl Derivatives (Dr. S. J. Holt and R. F. J. Withers), 1012
Esters (Phosphoric) : Paper Chromatography of (S. Burrows, F. S. M. Grylls and J. S. Harrison), 800
Estimation of Standard Deviations : Rapid (Dr. B. Woolf), 631
l'État solide : Réactions dans (Colloques Internationaux du Centre National de la Recherche Scientifique, 10, Paris, Octobre 1948), *review* by Prof. J. R. Partington, 944
Ethical Dilemma of Science (Prof. A. V. Hill), 388
Ethics of Management (H. E. Roff), 102
Ethics and the History of Philosophy (Prof. C. D. Broad), *review* by Prof. A. D. Ritchie, 992
Ethionine : Rapid Restitution of the Rat Pancreas following Acinar Cell Necrosis subsequent to (Dr. Patrick J. Fitzgerald and Dr. Mario Alvizouri), 929
Ethnography of Africa : Contribution to the (Sture Lagercrantz), *review* by G. I. Jones, 993
Euglena : Specificity of Vitamin B_{12} for (Dr. William J. Robbins, Annette Hervey and Mary E. Stebbins), 845
Europe : Bird Conservation in, 97
  Protection of Plants in, 143
European Brewery Convention—Proceedings of the Congress, Brighton, 1951, *review* by Dr. E. Barton-Wright, 901
European Broadcasting Conference at Stockholm, 185
European Congress for Chemical Engineering (To be made a permanent annual feature), 61
European Cortina-Ulisse Prize for 1952 awarded to Prof. E. H. F. Baldwin, 605
Evapotranspiration : A Simple Apparatus for Measuring Potential (Prof. B. J. Garnier), 286
Evolution : Embryology and, *review* by Prof. S. Zuckerman, 5
  Factors of (I. I. Schmalhausen), translated by Isadore Dordick, edited by Theodosius Dobzhansky, *review* by Prof. C. H. Waddington, 680
  Stabilizing Selection in, *review* by Prof. C. H. Waddington, 680
  Time and, *review* by N. W. Pirie, 992
  Time's Arrow and (Harold F. Blum), *review* by N. W. Pirie, 992
Evolution of Animal Fats (Dr. F. B. Shorland), 924 ; (Prof. T. P. Hilditch), 925
Evolution of Plant Species : Stages in the (Jens Clausen), *review* by Dr. W. B. Turrill, 385
Evolutionary Processes : Genetical Study of, *review* by Prof. K. Mather, 383
Ewe : Role of Progesterone in the Mating Behaviour of the (T. J. Robinson), 373
Ewing Gold Medal of the Institution of Civil Engineers awarded to Prof. J. F. Baker, 1100
Excitation of Ganglion Cells in the Inferior Mesenteric Ganglion by Collaterals (C. Job and Dr. A. Lundberg), 205
Excretion (Ketone-Body) : A Substance in Animal Tissues which stimulates (H. B. Stewart and Prof. F. G. Young), 976
Exhibition in Pharmacy : Devon and Cornwall, of the Pharmaceutical Society, awarded to A. James, 346
Expenditure (Public) : The Control of—Financial Committees of the House of Commons (Dr. Basil Chubb), 171 , *review* by R. Brightman, 337
Expenditure on Universities in Great Britain : State, 171
Experimentation : The Mathematics of, *review* by Dr. D. J. Finney, 991
Experimentation in Developmental Work : Principles Governing the Amount of (Dr. F. Yates), 138
Experiments : The Design and Analysis of (Prof. Oscar Kempthorne), *review* by Dr. D. J. Finney, 991
Experiments in Living, a Study of the Nature and Foundation of Ethics or Morals in the Light of Recent Work in Social Anthropology (Prof. A. Macbeath), *review* by Lord Raglan, 174
Explosion Limits (Second) : Effect of Withdrawal-Rate on (Sir Charles Egerton and D. R. Warren), 420
Explosions of Carbon Monoxide : Effect of Water Vapour on (D. E. Hoare and Dr. A. D. Walsh), 838
Extractability of the Lotmar-Picken Material from Dried Muscle (Dr. H. E. Huxley and Dr. J. C. Kendrew), 882
Extraction of Oils and Fats : The Chayen Process for (Dr. J. M. Coulson), 881
Extraction and Refining of Metals : Principles of the (Institution of Metallurgists), 405

Extractive Distillation : Vapour-Liquid Equilibrium Relationships in (Dr. E. F. G. Herington), 935
Eye (Compound) : Nerve Impulses originating from the, of the Locust (E. T. Burtt and W. T. Catton), 285
Eye (Human) : Accuracy and Sensitivity of the (Dr. M. H. Pirenne and Dr. E. J. Denton), 1039
Eye-Dominance : Measurement and Interpretation of (Margaret M. Clark), 192
Eye Rotations with Change of Accommodation (Dr. Mary P. Lord), 670

FACTORY : Moving a (Roy Lewis), 268
Fakes and Forgeries (Dr. H. J. Plenderleith), 354
Family Legislation : Soviet (Dr. R. A. J. Schlesinger), 274
FAO Memo (New publication of the Food and Agriculture Organization of the United Nations), 59
Farm (Small) : Problems of the (British Association for the Advancement of Science, Section M (Agriculture), Discussion on), 740
Farm Animals . A Fauna of, *review* by Dr. John Hammond, 260
Farm Management : Forestry in (R. H. Westveld and the late Ralph H. Peck), second edition, *review* by N. D. G. James, 551
Farm Water Supplies (Society for Applied Bacteriology Discussion on), 1107
Farming : Resistance to Change in (British Association for the Advancement of Science, Sections J (Psychology) and M (Agriculture), Symposium on), 688
Fats : The Chayen Process for Extraction of Oils and (Dr. J. M. Coulson), 881
  Hydrogenation of Oils and, *review* by Dr. H. Jasperson, 175
Fats (Animal) : Evolution of (Dr. F. B. Shorland), 924 ; (Prof. T. P. Hilditch), 925
Fatty Acid and Protein Monolayers : Tanning of, by Metal Ions (Cr, Al, Fe and Cu), (Dr. J. H. Schulman and M. Z. Dogan), 31
Fatty Acids (Volatile) : Origins of the, in the Rumen (F. V. Gray and A. F. Pilgrim), 375
Fatty Oils : Hydrogenation of (Prof. H. I. Waterman, with the collaboration of C. Boulhouwer and L. J. Revallier), *review* by Dr. H. Jasperson, 175
Fauna (Bottom) : Change in the Composition of the, of the Dogger Bank Area (Erik Ursin), 324
Fauna of Farm Animals, *review* by Dr. John Hammond, 260
Fellowship : Kathleen Schlesinger (Medical Research Council), 653
Fellowship in Synthetic Organic Chemistry established by Parke, Davis and Co., Detroit, at the Mellon Institute of Industrial Research, 484
Fellowship and Scholarships for work on Arctic or Sub-Arctic Research (McGill University and the Arctic Institute of North America), 695
Fellowships : Engineering Research (British Thomson-Houston Co., Ltd.), 59
  Merck (National Research Council, Ottawa, Awards), 189
  Ramsay Memorial, 60
  Wellcome Pharmaceutical Research, awarded to J. Thomas and G. L. Willey, 346
Fellowships to British Students for Advanced Study and Travel in the United States (Commonwealth Fund of New York), 524
Fellowships in Medicine : Eli Lilly Travelling (Medical Research Council Awards), 189
  Rockefeller Travelling (Medical Research Council Awards), 189
Fellowships in Microbiological Biochemistry : Guinness (University of Oxford), 693
Fellowships in Natural Science, Industrial Research, Virology and Agriculture (British Memorial Fund in Victoria, Australia), 189
Fellowships in Otology : Alexander Pigott Wernher Memorial Travelling (Medical Research Council Awards), 189
Fellowships in Statistics (University of Chicago), 653
Fellowships in Tuberculosis . Dorothy Temple Cross Research Travelling (Medical Research Council Awards), 189
Female Germ-Cells of *Lumbricus terrestris* L. : Extrusion of Nucleolar Material in the (D. S. Srivastava), 757
Fermentation : Carbohydrate, of Bacterial Isolates from Zygophyllaceous and Leguminous Root-Nodules (Prof. M. A. Mostafa), 276
Fermentation of similar Carbohydrates in Saccharomyces : Proximity of Genes controlling the (Prof. Carl C. Lindegren and Gertrude Lindegren), 965
Fern Callus : *In vitro* Cultures of a (Taylor A. Steeves and I. M. Sussex), 672
Ferritin in a Marine Elasmobranch, *Scyllium canicula* : Presence of (Dr. Giorgio Tecce), 75
Ferromagnetic Crystal with High Crystal Anisotropy : A New Method of Melting Ferromagnetic Semiconductors—$BaFe_{18}O_{27}$, a New Kind of (H. P. J. Wijn), 707
Ferromagnetic Semiconductors : A New Method of Melting—$BaFe_{18}O_{27}$, a New Kind of Ferromagnetic Crystal with High Crystal Anisotropy (H. P. J. Wijn), 707
Fertility (Society for the Study of Fertility Conference on), 231
Fertilized Rabbit Eggs exposed to Glycerol and to Low Temperatures : Behaviour of (Dr. A. U. Smith), 374
Fibre Processing : Moisture Relations and (Dr. J. L. Spencer-Smith), 732
Fibres, Old and New (British Association for the Advancement of Science, Section B (Chemistry), Discussion on), 865
Fibres : Artificial (R. W. Moncrieff), *review*, 818
Fibres (Protein) : The Reactivity of—some Analogies between Keratin and Collagen (Prof. J. B. Speakman), 1054
Fibres (Textile) : Moisture Relations and (British Association for the Advancement of Science, Section A (Physics), Discussion on), 732
Fibrin : The Conversion of Fibrinogen to (Dr. J. T. Edsall), 24
Fibrinogen : Interaction of Macromolecules and (F. Fletcher, L. E. Martin and A. H. Ratcliffe), 319
  The Conversion of, to Fibrin (Dr. J. T. Edsall), 24
Fibrinolytic Activator from Animal Tissue . Isolation of a Soluble (Dr. Tage Astrup and Agnete Stage), 929
Fibrinolytic Activity of Tissue Extracts and of Trypsin (Dr. Tage Astrup and Ida Sterndorff), 981
Field Strengths (Low) : Failure of Vacuum Insulation at (D. S. Clifford, R. L. Fortescue and J. Roberts), 503
Fields (High) : The de-Haas–van Alphen Effect at (Dr. D. Shoenberg), 569
Filarial Infections in Mosquitoes (N. G. S. Raghavan, B. G. Misra and Radhagovinda Roy), 253
Film in Education (Dr. Andrew Buchanan), *review*, 387
Film Research : Instructional (C. Denis Pegge), 962
Films : Emulsions and (British Society of Rheology Symposium on), 232
  List of 35-mm. and 16-mm. Documentary and Instructional (Petroleum Films Bureau), 608
  Silver, and Dielectric Multiple Films in Interferometry (Dr. D. A. Jackson and K. Kuhn), 455 ; (Dr. A. H. Jarrett), 456
Films (Evaporated Metal) : Russell Effect on (L. Grunberg and K. H. R. Wright), 456
Films (Metal) : Deposition of, on Jelly-like Materials (Edwin Rosenstiel), 85
Films in the University of Cambridge : Use of, 187
Films of Gold : Transparent Conducting, 236
Filter Paper . Quantitative Spot Test on, and Examples of its Application (Tetsuo Kariyone, Shuichi Shimizu and Dr. Yohei Hashimoto), 422
Filter Paper without a Colour Reagent : Ultra-Violet Papyrography—an Automatic Analytical Apparatus using (Dr. Yohei Hashimoto and Itsuhiko Mori), 1024
Filter Paper and other Media : Salting-out Chromatography of Amino-acids and Peptides in (L. Hagdahl and Prof. A. Tiselius), 799
Financial Committees of the House of Commons : The Control of Public Expenditure—(Dr. Basil Chubb), 171 ; *review* by R. Brightman, 337
Fish and Fisheries of Australia (T. C. Roughley), revised edition, *review* by G. A. Steven, 593
Fish Feeding on *Simulium* Larvae (Dr. G. Marlier), 496
Fish-Farming in Central Africa : Mollusc Control and (Dr. A. F. De Bont and M. J. De Bont Hers), 323
Fisheries of Australia : Fish and (T. C. Roughley), revised edition, *review* by G. A. Steven, 593
Fission of Uranium-235 . Possibility of the Quaternary (Prof. E. W. Titterton), 794
Fissuring of Wheat due to Weathering : Internal (Prof. Max Milner, J. A. Shellenberger, M. R. Lee and Robert Katz), 533
Flagellates : Fine Structure of Chloroplasts in Two (J. J. Wolken and G. E. Palade), 114
Flames : Twin (W. G. Berl and D. Dembrow), 367
Flames and Furnaces : The Science of (M. W. Thring), *review*, 769
Flattened Egg : Division of the (Prof. J. F. Danielli), 496
Flattening of Meniscus between Water and Organic Solvents (Dr. A. F. H. Ward and L. H. Brooks), 118
Flavin-adenine-dinucleotide . Total Synthesis of (S. M. H. Christie, Dr. G. W. Kenner and Prof. A. R. Todd), 924
Flavonoids and Sugars : Paper Electromigration of, using a High Constant-voltage Current (Dr. Yohei Hashimoto, Itsuhiko Mori and Mutsuo Kimura), 975
Flax . Botany of (British Association for the Advancement of Science, Section K (Botany), Discussion on), 557
Flax Plant : β-Oxidation of ω Phenoxyalkylcarboxylic Acids in the (C. H. Fawcett, J. M. A. Ingram and Prof. R. L. Wain), 887
Fleas, Flukes and Cuckoos (Miriam Rothschild and Theresa Clay), *review* by Dr. E. Hindle, 382
Fleming (Ambrose) Premium of the Institution of Electrical Engineers awarded to H. Stanesby, 19
Flight-Tone and Wing-Stroke Frequency of Insects and the Dynamics of Insect Flight (Dr. Olavi Sotavalta), 1057
Floor of the Eastern North Pacific Ocean : Heat Flow through the (Roger Revelle and Arthur E. Maxwell), 199 , (Dr. E. C. Bullard), 200
Flora : Arizona (Thomas H. Kearney, Robert H. Peebles and collaborators), *review* by Sir Edward Salisbury, 299
  Central American, 1003
Flora of Arizona, *review* by Sir Edward Salisbury, 299
Flora of Guatemala (P. C. Standley and J. A. Steyermark), 1003
Flora (Schweizer) . Taschenatlas der (Eduard Thommen), zweite Auflage, *review* by Prof. F. E. Weiss, 431
Flora (Swiss) : Pocket Atlas of the, *review* by Prof. F. E. Weiss, 431
Flora Malesiana (general editor, Dr. C. G. G. J. van Steenis), Series I, Spermatophyta, Vol. I, Malaysian Plant Collectors and Collections (Mrs. M. J. van Steenis-Kruseman), *review* by H. S. Marshall, 336
Florida Citrus : Molybdenum Deficiency in (Dr. Ivan Stewart and C. D. Leonard), 714
Flow Birefringence of Myosin as a result of Muscular Atrophy : Changes in the (Georges Schapira, Jean-Claude Dreyfus and Maurice Joly), 494
Fluids (Body) . Progesterone in (D. G. Edgar), 543
Flukes and Cuckoos : Fleas, (Miriam Rothschild and Theresa Clay), *review* by Dr. E. Hindle, 382
Fluorescence of Chlorophyll Solutions : Activation of the (Prof. Robert Livingston and Sanford Weil), 750
Fluorescence of Organic Compounds, *review* by Dr. E. J. Bowen, 296
Fluorescence Microscopy : Counting Soil Algae by Direct (Y. T. Tchan), 328
Fluorescent Lamps (Tubular) : Extreme Ultra-Violet Radiation from, and its Effect on Museum Lighting (J. Gerard), 306
Fluorescent Lighting in Museums, 306, 441
Fluoreszenz organischer Verbindungen (Prof. Theodor Forster), *review* by Dr. E. J. Bowen, 296
Flycatcher (Spotted) : Breeding Biology of the (D. Summers-Smith), 607
Flying-Spot Microscope (F. Roberts and Prof. J. Z. Young), 137
  High-Speed Counting with the (F. Roberts and Prof. J. Z. Young), *erratum*, 19
Focusing System for Van de Graaff Accelerating Tubes : A Versatile (P. Howard-Flanders), 744
Fodder Development in Mediterranean Countries : Pasture and (Prof. N. M. Comber), 56
Foetal Fructose in various Mammals (R. F. W. Goodwin), 750
Folic Acid Deficiency . A Sparing Effect by Formate or Methanol on the Impairment of Creatine Metabolism in (Prema Fatterpaker, Urmila Marfatia and Dr. A. Sreenivasan), 894
Folklore and Sacred Tradition . Archaeology, (Prof. E. O. James), 397
Food : Townsman's (Dr. Magnus Pyke), *review* by Dr. L. H. Lampitt, 552
  World Population and, *review* by Miss M. W. Grant, 259
Food and the Future (Nutrition Panel of the Food Group of the Society of Chemical Industry Symposium on), 956
Food for the Urban Masses, *review* by Dr. L. H. Lampitt, 552
Food Preservation : Aspects of (Symposium on, at the Summer Conference of the Society for Applied Bacteriology), 444
Food Processing : Chemistry and (British Association for the Advancement of Science, Section B (Chemistry), Discussion on), 603
Food Research : Advances in (edited by E. M. Mrak and George F. Stewart), Vol. 3, *review* by A. T. Parsons, 690

Food Science at Home and Overseas (Institute of Rural Life at Home and Overseas, the Association of Agriculture and the University of London Institute of Education Meeting on), 829
Food Supplies : Britain's (Dr. N. C. Wright), 400
  Symposium on, 956
Food Technology: Problems and Possibilities in, *review* by A. T. Parsons, 680
Foods for Human Consumption . Unusual (Nutrition Society Symposium on), 1050
Foot-and-Mouth Disease in Great Britain (Ministry of Agriculture and Fisheries Committee on), 406
Foot-and-Mouth Disease Research in Great Britain, 908
Forbidden Transitions in Atoms (A. G. Shenstone), 832
Forbidden Transitions in Diatomic Molecules (Dr. G Herzberg), 832
Forbidden Transitions in Nuclei (L. G. Elliott), 832
Foreign Relations : Science and (United States Department of State, Publication 3860), 1033
Forest Taxation in New Zealand (M. B. Grainger), 482
Forestry : Agriculture and, 562
  The Alternative to Extensive Regular Clear-Felling in (M. J Penistan), 607
  Estate (Sir William Ling Taylor) *review* by N. D. G. James, 471
Forestry in Farm Management (R. H. Westveld and the late Ralph H Peck), second edition, *review* by N. D. G James, 551
Forests in S W. Germany : The Sylviculture of Mixtures in some (F. C Hummel), 652
Forficula auricularia : Seasonal Change in the Humidity Reaction of the Common Earwig (Dr. Vilho Perttunen), 209
Forgeries : Fakes and (Dr. H. J. Plenderleith), 354
Form Problem : Botanical Aspects of the *review* by Prof Edmund W. Sinnott, 990
Formaldehyde under Mild Conditions : Colorimetric Determination of (T. Nash), 976
Formalin . Viability of *Conispiculum guindiensis* in *Calotes versicolor* Preserved in (N. G. S. Raghavan) 125
Formate or Methanol : A Sparing Effect by, on the Impairment of Creatine Metabolism in Folic Acid Deficiency (Prema Fatterpaker, Urmila Marfatia and Dr. A. Sreenivasan), 894
Formation of Indole by *E coli* : Competitive Action of Isonicotinic Acid Hydrazide and Vitamin B_6 in the (Masahiko Yoneda, Nobuo Kato and Mitsuharu Okajima), 803
Formation and Breakdown of Pentose Phosphates by Liver Fractions (Dr. Gertrude E. Glock), 162
Formation Constants of some Metal-Tropolone Complexes (Burl E. Bryant, Prof. W. Conard Fernelius and Bodie E. Douglas), 247
Four-strand Crossing-over (Dr. A. R. G. Owen), 985 ; (Dr. T. C Carter and Dr. Alan Robertson), 986
Fourier Syntheses (Optical) : Improvements in (A. W. Hanson), 380
Fracture of Alloy Steel : Delayed Brittle, at Low Stress Levels (C L. M. Cottrell), 1079
Fracture of Concrete : Mechanism of (Dr. Frank A. Blakey), 1120
Framework of Joint Consultation (J. H. Smith and Miss R. J. Carey), 255
Franklin's 'Philadelphia Experiment' on Lightning, 1099
Freedom : Academic, in the Modern State, 721
  Scientific, and Security, 215
Freedom and Responsibility (Present Question Conference on), 217
Freezing and Drying : Report of a Symposium held in June 1951 (Institute of Biology), *review* by Dr. Geoffrey H. Bourne, 723
Freezing and Drying Tissues : Edmond About and the Technique of (L. G. E. Bell), 547 ; (R Legendre), 1080
French Bibliographical Digest : No. 7, Physics, No. 8, Chemistry, 227
French Electronic Instrumentation : Progress in, 441
French Exchange Scholarships in Medical Science (Medical Research Council Awards), 189
Frequency Factor . Relation between Activation Energy and (Dr. M. Szwarc and D. Williams), 290
Freshwater Life of the British Isles (John Clegg), *review* by H C. Gibson, 681
Frog's Liver (*Rana temporaria*) : Environmental Temperature and the Glycogen Content of the (Dr. C. L. Smith), 74
Fructose in various Mammals : Foetal (R. F. W Goodwin), 750
Fruit Crops: Virus Diseases of (Dr. A. F. Posnette and Dr. R. V. Harris), 181
Fruit Trees : Chlorogenic Acids in (Dr. A. E. Bradfield A E Flood, A C. Hulme and A. H. Williams), 168
Fucose by a New Reaction : Sugar Components of Blood and Urinary Glycoproteins—Confirmation of the Presence of (Deirdre M. Waldron), 461
Fuel in Britain : Utilization of, 589
Fuel Problems in Great Britain : National, 827
Fugle . Grønlands (The Birds of Greenland), (text by Finn Salomonsen, plates by Gitz-Johansen), Part 3, *review* by Sir Norman Kinnear, 639
Fulbright Programme : Travel grants under the (United States Educational Commission in the United Kingdom), 784
Fulmar : The (James Fisher), *review* by R. M. Lockley, 725
Fumigant (Soil) : Tainting of Tobacco by a Dichloropropene-Dichloropropane (C. J. Shepherd), 1073
Fumigant Action of Non-volatile Insecticides in African Huts : Apparent (G. Davidson and G. F Burnett), 893
Function (Error) : Tables of the, and of its First Twenty Derivatives (Staff of the Computation Laboratory of Harvard University), *review* by Prof. W. G Bickley, 1089
Fungi . Classification of the (Linnean Society Discussion on), 997
  Detection of Radiophosphorus in Cells and Spores of, by Radioautography (A. M. Adams and J. J Miller), 239
Fungi for Everyone, *review* by Dr. J. Grainger, 1088
Fungi and Bacteria, etc , caught in the Air during Flights over the Geographical North Pole . Arctic Aerobiology— (Prof. Nicholas Polunin and Dr. C. D. Kelly), 314
Furnace Technology : Scientific Principles of, *review*, 769
Furnaces : The Science of Flames and (M. W. Thring), *review*, 769
Fusarium solani : Soil Bacteria and Chlamydospore Formation in (C. S. Venkat Ram), 889

GALACTIC Structure. Variable Stars and (Cecilia Payne-Gaposchkin), 223
Gamma-Ray Pinhole Camera : Use of a, for *in vivo* Studies (H. O. Anger), 200
Gamma-Ray Radioactivity : Beta- and (Netherlands Physical Society, the International Union of Pure and Applied Physics, and Unesco, Conference on), 229
Gamma-Ray Sources for Radiography (Industrial Radiology Group of the Institute of Physics Memorandum on), 186
γ-Rays of Radium-D (Dr. George T. Ewan and Dr. M. A. S. Ross), 760
Ganglion Cells in the Inferior Mesenteric Ganglion : Excitation of, by Collaterals (C. Job and Dr. A. Lundberg), 205
Ganglion Depressant Properties of Barbiturates : Autonomic (K. A. Exley), 242
Ganglion Neurones (Spinal) : Senility Changes in the, of the Toad, *Bufo regularis* (Dr. Tohamy A Moussa), 206
Ganglionic Blocking Agents : Comparison of (J. F. Mainland and Dr. F. H. Shaw), 418
Gardner's Hypothesis and the Michelson–Morley Experiment (Prof. J. L. Synge), 243
Gaseous Contamination of Geiger–Müller Counters (D. Keefe, Dr. T. E Nevin, Prof. C. B. A. McCusker and N. A. Porter), 501
Gases : Electrical Discharges in (British Association for the Advancement of Science, Section A (Mathematics and Physics), Discussion on), 601
Gaster (Leon) Memorial Premium of the Illuminating Engineering Society awarded to J. S McCulloch, 651
Gastric Secretion of Hydrochloric Acid *in vivo* . Inhibition of, by Carbonic Anhydrase Inhibition (Henry D. Janowitz, Henry Colcher and Franklin Hollander), 499
Gastropod Veligers : Efficiency of Growth in *Mytilus edulis* and Two (C. Barker Jørgensen), 714
Geiger–Muller Counters : Gaseous Contamination of (D. Keefe, Dr. T. E. Nevin, Prof. C. B A. McCusker and N. A. Porter), 501
Gel (Silica) : Chromatography of Rubber Accelerators and Anti-Oxidants on (Dr. C. A Parker), 539
Gelatine Films : The Effect of the Temperature of Preparation on the Mechanical Properties and Structure of (E. Bradbury), 24
Genes controlling the Fermentation of similar Carbohydrates in Saccharomyces : Proximity of (Prof. Carl C. Lindegren and Gertrude Lindegren), 965
Genetic Basis for an Acquired Character : Selection of the (Prof. Paul G. 'Espinasse), 71
Genetical Study of Evolutionary Processes, *review* by Prof. K. Mather, 383
Genetical System admitting of Two Stable Equilibria (Dr. A. R. G. Owen), 1127
Genetics . Human Biochemical (British Association for the Advancement of Science, Sections D (Zoology), I (Physiology), J (Psychology) and K (Botany), Discussion on), 654
Genetics and the Origin of Species (Prof. Theodosius Dobzhansky), third edition, *review* by Prof. K. Mather, 383
Genotypical Background of Resistance to *Heterodera rostochiensis* in *Solanum tuberosum* var. *andigenum* (Dr. H. J Toxopeus and C. A. Huijsman), 1016
Geographical Congress : Seventh International, 347 ; (Prof. L. Dudley Stamp), 961
  Presidential Address (Dr. George Cressey), 962
Geography in the Making—the American Geographical Society 1851–1951 (John Kirtland Wright), *review*, 89
Geography in Secondary Schools : The Teaching of (Geographical Association Memorandum), 187
Geography of Hunger (Josué de Castro), *review* by Miss M. W. Grant, 259
Geological Research : Some Aspects of, and their Practical Application (Dr. J. E. Richey), 394
Geological Sites : Preservation of—Bilston Glen, 855
Geometry : Exhibition of, arranged by the Illinois Institute of Technology at the Chicago Museum of Science and Industry, 103
  You will like (Prof. Karl Menger), 103
Geometry and the Imagination (D. Hilbert and S. Cohn-Vossen), translated by P. Nemenyi, *review*, 1089
Geophysical Methods : Prospecting by (European Association of Exploration Geophysicists Conference on), 230
Geophysical Research aboard the R.R.S. *Discovery II*, 17
Geophysical and Meteorological Changes in the Period January–April 1949 (R. P. Waldo Lewis and D. H McIntosh), 488
George III Collection of Scientific Instruments : Descriptive Catalogue of the (Science Museum), 405
German Medical and Scientific Periodicals . Cost of (Dr. W Bonser and Margaret P. Russell), 446
Germany (South-West) : The Sylviculture of Mixtures in some Forests in (F. C Hummel), 652
Giant Nerve Cells in *Lingula* (P. Kirtisinghe), 206
Gifford Lectures for 1948–1949 (Prof. A. Macbeath), *review* by Lord Raglan, 174
Glands (Ductless) : Functions of the—Fiftieth Anniversary, 871
Glasgow . Employment Problems of Disabled Youth in (Medical Research Council Committee on the Resettlement of the Disabled Memorandum on), 833
Glass Layers as Supports for Electron Microscopy . Thin (Prof. A Van Itterbeek, L. De Greve, G. F. Van Veelen and C. A. F. Tuynman), 795
Glass-Polisher's Art, *review* by H. W. Lee, 553
Gliotoxin in Unsterilized Soil : Production of (Joyce M. Wright), 673
Glucose . Survival of the Perfused Cat's Brain in the Absence of (A Geiger, J. Magnes and R. S. Geiger), 754
Glucose-6-Phosphate Dehydrogenase in the Pea Plant : Triosephosphate Dehydrogenase and (Dr. Martin Gibbs), 164
Glucose-6-Phosphate Dehydrogenase Activity of Rat Liver (Dr. G. E. Glock and P McLean), 119
Glucuronide Decomposition in the Digestive Tract (C A. Marsh, F. Alexander and Dr. G. A. Levvy), 163
Glue Testing at Risborough (R. A G. Knight), 25
Gamma Glutamyl Activation of Peptide-Bond Synthesis : Reported (Richard W. Hendler and Prof. David M. Greenberg), 123
Glutathione : Enzymic Splitting and Synthesis of (P. J. Fodor, A. Miller and Dr. H. Waelsch), 841
Glutathione Content : Relationship between Reduced, and Spontaneous Haemolysis in Shed Blood (Dr. G. Fegler), 624
Glycerol : Behaviour of Fertilized Rabbit Eggs exposed to, and to Low Temperatures (Dr. A. U. Smith), 374
Glycerol as a Nutritive for *Vibrio cholerae* (Dr. Deborah Kaplan and Dr. Walter Koch), 165

Glycyl-L-Leucine in Normal and Neoplastic Tissues : Effect of D(+)-Leucine on the Hydrolysis of (Prof. A. Vescia, A. Albano and A. Iacono), 804
Glycogen : Action of Salivary α-Amylase on Amylopectin and (Dr. W. J. Whelan and P J. P. Roberts), 748
Glycogen Content of the Frog's Liver (*Rana temporaria*) : Environmental Temperature and the (Dr. C. L. Smith), 74
Glycogens Molecular Weight of, determined by a Light-scattering Method (B S. Harrap and D. J. Manners), 419
cis-trans 1-2 Glycols : Histochemical Differentiation of (Dr. John F. Lhotka), 751
Glycoproteins (Blood and Urinary) : Sugar Components of—Confirmation of the Presence of Fucose by a New Reaction (Deirdre M. Waldron), 461
Gylcosides (Digitalis), Detection of, on Paper Chromatograms (Dorothy Lawday), 415
Glycyl-L-Asparagine Configuration of the Peptide Link and of Asparagine in (Dr. Lewis Katz, R A. Pasternak and Prof. Robert B. Corey), 1066
Gnetales and Ephedrales : New Light on (Prof. A. J. Eames), 1099
Gold : Transparent Conducting Films of, 236
Gold Coast Timbers (D. Kinloch and W. A Miller), revised edition, 563
Golgi Substance in Epithelial Cells of the Epididymis . 'Lipochondria' and the (A. J Dalton and Marie D. Felix), 541
Government (Local) : National Parks and, 333
Government of British Trade Unions (Dr Joseph Goldstein), 812
Government Research in Australia—Commonwealth Scientific and Industrial Research Organization, 565
Grading Microscopic Spherical Particles A Method of Measuring and (Dr. V. Timbrell), 318
Grain Detection of Insects in, 562
Grant in aid of Universities and Colleges (Fifth Report from the Select Committee on Estimates), 171
Graphite Spiral Growth on (F. Hubbard Horn), 581
Graphite in Cast Irons Crystal Distortion of (Eitaro Maruyama), 1123
Grass (*Trachypogon plumosus* (H. B. K.) Nees) and of *Pentanisia variabilis* (E Mey.) Harv (Rubiaceae) : Production of Antibiotic Substances by the Roots of a (Gordon Stiven), 712
Grasshopper Chromosomes . Electron Microscope Study of (A. Guha, M L. De and S. P. Ray-Chaudhuri), 360
Gravitational Instability of a Turbulent Medium (Dr E. N Parker), 1030
Gravity Observations in a Borehole (R. L. G Gilbert), 424
Great Britain : Broadcasting and Television in, 45
  Foot-and-Mouth Disease in (Ministry of Agriculture and Fisheries Committee on) 406
  Foot-and-Mouth Disease Research in, 908
  Incentives and Size of Industrial Plant in (Dr. W Baldamus), 112
  Lepine and Sautter's Disease in (Dr R. Hadek), 165
  National Fuel Problems in, 827
  Newspaper Libraries in, 563
  Petroleum Consumption and Refinery Production in, during 1951 (Petroleum Information Bureau), 268
  State Expenditure on Universities in, 171
  Transport in, 697
  Universities and University Colleges in, 873
  Weights and Measures in, 1001
  See also under Britain
Greece Archæology in, 1950–51 (J M Cook), 269
Greenland . Birds of, *review* by Sir Norman Kinnear, 639
Greenwich Mean Time, 738
Gregarious Æstivation in the Bogong Moth, *Agrotis infusa* : Migration and (I. F. B. Common), 981
Gromwell (Cultivated) . Inhibition of Œstrus by (Dr B. P. Wiesner and Prof. John Yudkin), 274
Grönlands Fugle (The Birds of Greenland), (text by Finn Salomonsen, plates by Gitz-Johansen), Part 3, *review* by Sir Norman Kinnear, 639
Ground : Spore Content of the Atmosphere near the (P. H. Gregory), 475
Groundnuts Scheme in East Africa, 782
Growing-Points in Cytology, 655
Growth of Excised Maize Embryos : Effect of Tissue Cultures of Maize Endosperm on the (Elizabeth A. Pieczur), 241
Growth in *Mytilus edulis* and Two Gastropod Veligers Efficiency of (C Barker Jorgensen), 714
Growth of Protozoa (New York Academy of Sciences and the Society of Protozoologists Conference on), 406
Growth of Rat Ovary in Tissue Culture (Jean I. Scott), 208
Growth Interaction between β-Indolylacetic Acid and Thiourea (Thiocarbamide), (D Wynn Parry), 1074
Growth Spirals and their Relation to Crystal Habit as illustrated by Apatite (S Amelinckx), 760
Growth Spirals originating from Screw Dislocations on Electrolytically produced Titanium Crystals (M A. Steinberg), 1119
Growth Substances : Early Effects of (Prof. L. G. M Baas Becking and R G Everson), 1019
Growth-Factor . A Bacterial, Synthesized by a Soil Bacterium (A. G. Lochhead, Margaret O Burton and R H. Thexton), 282
Growth Factor Requirements of *Pellicularia koleroga* Cooke in Pure Culture (K. T. Mathew), 889
Guatemala : Flora of (P. C. Standley and J. A. Steyermark), 1003
Guinness Research Fellowships in Microbiological Biochemistry (University of Oxford), 693

HÆMAGGLUTINATION (Influenza Virus) : Carbohydrate Residue of a Urine Mucoprotein inhibiting (Dr. Alfred Gottschalk), 662 ; (Dr. L. Odin), 663
Hæmagglutinins present in the Seeds of *Dolichos biflorus* . Relationship of the Blood Sub-Groups A_1, A_2 and A_1B, A_2B to (Lieut.-Colonel G W G. Bird), 674
Hæmoglobin and its Derivatives Effect of Drying upon the Absorption Spectra of (Prof. D Keilin and Dr. E. F. Hartree), 161
Hæmolysis in Shed Blood : Relationship between Reduced Glutathione Content and Spontaneous (Dr. G. Fegler), 624
Hæmolytic and Surface Activity of Sodium Taurocholate (B. A Pethica and Dr J H. Schulman), 117
Hæmopoiesis : Biochemistry of (Symposium on, at the Second International Congress of Biochemistry), 443
Halloysite : Sedimentation of (Ian McDowall and W. Vose), 368
Hanbury Memorial Medal of the Pharmaceutical Society awarded to Prof Gosta Edman, 953
Haploid and Diploid *Aspergillus* Conidia : Deoxyribonucleic Acid Content of (Dr. F. C. Heagy and Dr. J. A. Roper), 713
Hardness of Metals (D. Tabor), *review* by Prof. A. G Quarrell, 818
Hatchery Practice Incubation and, 562
Hay : A Factor in Inhibiting the Action of Vitamin D (J. Weits), 891
Health of the School Child (Report for 1948–49 of the Chief Medical Officer to the Ministry of Education), 111
Health Congress (Royal Sanitary Institute) 442
Heart-beat in Tunicates : Reversal of the (Dr. R. H Millar), 851
Heart-Muscle Sarcosomes . Stabilization of Oxidative Phosphorylation in (Dr. E. C. Slater and Dr. K. W. Cleland), 118
Heat . Agglutination Reactions in Human Red Cells fragmented by (Ruth Ponder and Dr. Eric Ponder), 928
Heat Energy : Conveying of, *review* by D. B. Spalding, 509
Heat Flow through the Floor of the Eastern North Pacific Ocean (Roger Revelle and Arthur E. Maxwell), 199 ; (Dr. E. C. Bullard), 200
Heat Transfer and Insulation : Elements of (Prof. Max Jakob and Prof. George A. Hawkins), second edition, *review* by D. B Spalding, 509
Heat and Mass : Introduction to the Transfer of (E. R. G. Eckert), *review* by D B. Spalding, 1089
Heating (Domestic) : The Science of (J S. Hales), 302
Heats of Formation of Mercury Dimethyl, Diethyl and Diphenyl and some Associated Bond Dissociation Energies (A S Carson, Mrs E. M Carson and B. Wilmshurst), 320
Heavy Water . Physical Properties and Analysis of (Isidor Kirshenbaum), edited by Harold C Urey and George M Murphy, *review* by Prof. H. J Emeleus, 635
Hekla Pumice from Denmark : Sub Fossil (Prof. A. Noe-Nygaard), 227
Hen's Egg : Electrical Resistance and Structure of the (D. M. Maurice), 495
  Permeability of Yolk of the to Bromine-82 (D. M. Maurice and A Fidanza), 546
Herbicides (Hormone) Detoxication of, by Soil Bacteria (Dr H L. Jensen and H. Ingv. Petersen), 39
Hertz (Heinrich) Premium of the British Institution of Radio Engineers awarded to R. E. Spencer, 308
Heterocyclic Compounds, *review*, 384
Heterocyclic Nitrogen Compounds with Four Condensed Rings Six-Membered (C. F. H. Allen, in collaboration with D. M. Burness, Jean V. Crawford, P. W. Spangler, Eleanor R Webster and C. V Wilson), *review*, 384
Heterodera rostochiensis : Genotypical Background of Resistance to, in *Solanum tuberosum*, var. *andigenum* (Dr H. J. Toxopeus and C A Huijsman), 1016
Heterodera rostochiensis Wollenweber Resistance to the Potato Root Eelworm (Dr C. Ellenby), 1016
Heterogeneous Equilibrium The Phase Rule and (Prof. John E. Ricci), *review* by Prof J R Partington, 859
Heterosis . Heterozygosity, Environmental Variation and (Dr Forbes W Robertson and Dr. E. C. R. Reeve), 286
Heterothallic *Saccharomyces cerevisiae* . Single-spore Cultures of, which mate with both the Tester Strains (Dr. M Ahmad), 546
Heterothallism : The Terms Homothallism and (Dr. R P Korf), 534
Heterozygosity, Environmental Variation and Heterosis (Dr Forbes W Robertson and Dr E. C R. Reeve), 286
Heterozygous Diploid *Aspergillus* Non-random Distribution of Multiple Mitotic Crossing-over among Nuclei of (Dr G Pontecorvo), 204
Hibiscus sabdariffa, L.N.P.5 : Photoperiodic Behaviour of (Sumitra Talukdar), 458
High Molecular Weight Solutes : Use of, in the Study of Isolated Intracellular Structures (Dr. John H. McClendon and Prof. L R Blinks), 577
Histamine, Arsenic Acid and Dichlorophenoxyacetic Acid : Phytotoxicity of, and Methods of Testing (C. G Greenham), 535
Histochemical Demonstration of Alkaline Phosphatase . Coupling Azo Dye Methods for (Dr. E Grogg and Dr. A G. Everson Pearse), 578
Histochemical Differentiation of *cis trans* 1-2 Glycols(Dr. John F. Lhotka),751
History of Philosophy Ethics and the (Prof. C. D. Broad), *review* by Prof. A. D. Ritchie, 992
Home and Overseas : Food Science at (Institute of Rural Life at Home and Overseas, the Association of Agriculture and the University of London Institute of Education Meeting on), 829
Homing Ability in Birds (G. V. T. Matthews), 237 ; (Gustav Kramer), 237
Homografts (Adrenal Gland) . Survival of, in the Rabbit's Skin (Dr. D A. Darcy), 805
Homolytic Decomposition of Aldehydes Thiol Catalysis of the (Dr E. F. P. Harris and Dr. W A Waters), 212
Homothallism and Heterothallism : The Terms (Dr. R. P Korf), 534
Honeybee Colony . New Evidence of Communication in the (C R Ribbands, Dr. H. Kalmus and H. L. Nixon), 438
Honeydew of *Myzus circumflexus* (Buck) : Occurrence of Gamma Amino-Butyric Acid in Extracts of *Pisum sativum* (L) and in the (J L. Auclair and J. B. Maltais), 1114
Hop Cone : Influence of Mineral Nutrition on the Resin Content of the (F. C Thompson and Dr. A H. Burgess), 890
Hopkinson (John) Premium of the Institution of Electrical Engineers awarded to T. H. Flowers, 19
Hormone (Prof. W. von Buddenbrock), (Vergleichende Physiologie, Band 4), *review*, 858
Hormone Research : Recent Progress in (Proceedings of the Laurentian Hormone Conference), Vol 5 (edited by Gregory Pincus), *review*, 858
Hormone Herbicides : Detoxication of, by Soil Bacteria (Dr. H L. Jensen and H. Ingv. Petersen), 39
Hormones. a Survey of their Properties and Uses (Pharmaceutical Society of Great Britain), *review* by Dr R. K. Callow, 593
Hormones The (edited by Gregory Pincus and Kenneth V Thimann), Vol. 2, *review*, 858
  Adrenal Cortical, in Human Placenta (Constance de Courcy, Prof. C. H. Gray and J Barbara Lunnon), 494
  Survey of, *review* by Dr. R. K. Callow, 593
Hormones (Steroid) : A Symposium on (edited by Edgar S Gordon), *review*, 858
Hormones in Plants and Invertebrates . The Action of (edited by Kenneth V. Thimann), *review* by Dr. Arthur W. Galston, 724
Hormones related to Proteins (Symposium on, at the Second International Congress of Biochemistry), 443

Hormones, Chemotherapy and Antibiotics, *review* by Prof. J. W. Cook, 1086
Hormones and Tumors Steroid (Dr. Alexander Lipschütz), *review* by Dr. A. S. Parkes, 178
Horses (George Gaylord Simpson), *review* by Prof. D. M. S. Watson, 856
Horticultural Congress; Thirteenth International (Royal Horticultural Society), 187; (Patrick M. Synge), 647
Hot Springs Biology of, *review*, 134
Hothersall Memorial Medal and Lecture of the Institute of Metal Finishing endowed by the Mond Nickel Co., Ltd., 229
House Mouse A New Linkage in the—Vestigial and Rex (Donald Michie), 585
Household Science: University Degrees in Nutrition and, 226
Household Standards of Living in Less-Developed Areas. Enquiries into (United Nations Department of Social Affairs) 529
Housing in the U.S.S.R. (Dr. E. M. Chossudovsky), 351
Hughes Medal of the Royal Society awarded to Prof. P. I. Dee, 826, 948
Human Anatomy: Atlas of (Franz Frohse, Max Brodel and Leon Schlossberg), new edition, *review* by Prof. W. J. Hamilton, 178
Human Behaviour. Factors influencing Change in, 688
Human Biochemical Genetics (British Association for the Advancement of Science, Sections D (Zoology), I (Physiology), J (Psychology) and K (Botany), Discussion on), 654
Human Blood Group *A* and *B* Substances Serological Properties of (R. A. Gibbons and Prof. W. T. J. Morgan), 77
Human Blood Groups (Dr. F. Stratton), 821
Human Consumption: Unusual Foods for (Nutrition Society Symposium on), 1050
Human Erythrocytes · Electron Microscope Studies on Thin Sections of (W. Bernhard), 359
Human Eye: Accuracy and Sensitivity of the (Dr. M. H. Pirenne and Dr. E. J. Denton), 1039
Human Placenta · Adrenal Cortical Hormones in (Constance de Courcy, Prof. C. H. Gray and J. Barbara Lunnon), 494
Human Red Cells fragmented by Heat · Agglutination Reactions in (Ruth Ponder and Dr. Eric Ponder), 928
Human Relations in Industry (Report of the Conference arranged by the Ministry of Labour and National Service), 652
Human Seminal Fluid Pepsinogen in (Dr. Frank Landquist and Dr. Hans Henrik Seedorff), 1115
Human Serum: A Relationship between the Secretion of the Blood Group Antigens and the Presence of anti-*O* or anti-*H* in (Dr. Ruth Sanger), 78
Human Skin: Localization of Erythermal Processes caused by Ultra-Violet Light in (P. B. Rottier and J. A. M. Mullink), 574
Human Starvation: The Biology of (Ancel Keys, Josef Brozek, Austin Henschel, Olaf Mickelsen, Henry Longstreet Taylor), *review* by Dr. E. M. Widdowson, 177
Human and Pig Strains of *Ascaris* · Anatomical Distinction between (Dr. J. F. A. Sprent), 627
Humidity Reaction of the Common Earwig, *Forficula auricularia* Seasonal Change in the (Dr. Vilho Perttunen), 209
Humidity Response of *Tenebrio* Effect of Desiccation on the (S. E. Dodds and Dr. D. W. Ewer), 758
Hundred Years of Anthropology (T. K. Penniman), second edition, *review* by Dr. R. F. Fortune, 1037
Hunger: Geography of (Josué de Castro), *review* by Miss M. W. Grant, 259
Hyaluronidase: Enhancement of Streptococcal Bacteriophage Lysis by (W. R. Maxted), 1020
  Inhibitors of (L. Hahn), 282
Hydrates Thermal Transformations of the Aluminas and their (Margaret K. B. Day and Vernon J. Hill), 539
Hydrochloric Acid *in vivo* Inhibition of Gastric Secretion of, by Carbonic Anhydrase Inhibition (Henry D. Janowitz, Henry Colcher and Franklin Hollander), 499
$H\alpha$: Great Intensity Variations of, and Effects in Auroral Spectrograms taken in Rapid Succession (Prof. L. Vegard), 536
Hydrogen Lines (Auroral): Enhancement of, towards Lower Latitudes (Prof. L. Vegard), 1120
Hydrogen Peroxide produced by Lactobacilli Possible Identity of 'Lactobacillin' with (Dorothy M. Wheater Dr. A. Hirsch and Dr. A. T. R. Mattick), 623
Hydrogen Transfer by Thiols (Dr. A. F. Bickel and Dr. E. C. Kooijman), 211
Hydrogen–Oxygen Reaction Sensitized by Nitrosyl Chloride (J. Chanmugam and Dr. P. G. Ashmore), 1067
Hydrogenation of Fatty Oils (Prof. H. I. Waterman, with the collaboration of C. Boelhouwer and L. J. Revallier), *review* by Dr. H. Jasperson, 175
Hydrology of the Arid Zone (Unesco, with the Government of Turkey, Symposium on), 300
Hydrolysis of Glycil-L-Leucine in Normal and Neoplastic Tissues Effect of D(+)-Leucine on the (Prof. A. Vescia, A. Albano and A. Iacono), 804
Hydrolysis and Metabolism by Soil Bacteria of Benzoyl Derivatives of D- and L-Forms of some Amino-acids (Prof. Yukio Kameda, Etsuko Toyoura, Hiroshi Yamazoe, Yukio Kimura and Yoshiro Yasuda), 888
Hydroperoxides (Alkyl). Preparation of (Dr. A. G. Davies and A. M. White), 668
Hydropsyche angustipennis (Curtis) (Trichoptera) · Observation of Egg-laying under Water of the Aerial Insect (Ruth M. Baldwin), 40
Hydroxamic Acids. New, as Antitubercular Agents (Prof. T. Urbanski, S. Hornung, S. Slopek and J. Venulet), 753
3-Hydroxykynurenine: Relation of, to the Ehrlich Diazo Reaction of Urine in Severe Tuberculosis (Dr. Katashi Makino, Kiyoo Satoh, Tatsuo Fujiki and Kazuo Kawaguchi), 977
Hydroxyproline in Leaves Proline and (Prof. K. V. Giri, K. S. Gopalkrishnan, A. N. Radhakrishnan and C. S. Vaidyanathan), 579
Hyoid Arch of Rhinobatidae (A. R. Hamdy), 166
Hypochlorite (Alkaline) Action of, on 3.5.6-Trimethyl-*d*-gluconamide (Dr. K. S. Dodgson and Dr. J. Pryde), 35
Hypoglycaemic Convulsions Relief of, with Butyric Acid (B. J. Potter), 541
Hypophysectomized Killifish. Induction of a Spawning Reflex in (Grace E. Pickford), 807
Hysteresis in Rubber (D. M. Davies), 937

IDENTIFICATION of Organic Compounds from Infra-Red Spectra (Dr. A. E. Martin), 20
Identification of Tertiary Pollen Grains with those of New Guinea and New Caledonian Beeches (Dr. Isabel C. Cookson), 127
Identification of Uric Acid and Ascorbic Acid by Chromatography (Dr. F. Bode and H. J. Hübener), 501
Identification and Assay of Vegetable Drugs · Ash Pictures in the (Prof. Gösta Edman), 954
Identity of *Polystictus* (= *Polyporus* = *Trametes*) *cinnabarinus* (Jacq.) Fr. with *Polystictus sanguineus* (L.) Fr. (Prof. S. R. Bose), 1020
Igneous Ring-Complexes in Southern Nyasaland: A New Province of (K. V. Stringer), 630
Illuk Grass (*Imperata arundinacea*) Pulping of, by Soda and Mono Sulphite Processes (Chattar Singh and Dr. S. R. D. Guha), 27
Image (Stabilized Retinal) · Vision with a (Prof. R. W. Ditchburn and B. L. Ginsborg), 36
Imagination: Geometry and the (D. Hilbert and S. Cohn-Vossen), translated by P. Nemenyi, *review*, 1089
Immunity and Breeding of Cultivated Plants · The Origin, Variation, (Selected writings of N. I. Vavilov), translated from the Russian by Dr. K. Starr Chester, *review* by Prof. S. C. Harland, 48
Impact of Science on Society (Bertrand Russell), *review* by R. Brightman, 468
In vivo Studies: Use of a Gamma-Ray Pinhole Camera for (H. O. Anger) 200
Inactivation of DDT by Soils (A. B. Hadaway and F. Barlow), 762
Incentives and Size of Industrial Plant in Great Britain (Dr. W. Baldamus), 112
Incubation and Hatchery Practice, 562
Indeterminacy: Relativity and (Dr. G. W. Scott Blair), 582; (C. O. Hines), 582: (H. Bondi and T. Gold), 582
Indian Apple-Snail, *Pila globosa* (Swainson). Uricotelism in the common (Dr. M. B. Lal and B. B. Saxena), 1024
Indian Mammals, 1758 to 1946 Checklist of Palaearctic and (J. R. Ellerman and T. C. S. Morrison-Scott), *review* by Dr. L. Harrison Matthews, 298
Indian Water Buffalo: Chromosomes of the (M. K. Dutt and P. Bhattacharya), 1129
Indicator Spray for Amino-Acids (A. R. Kemble and H. T. Macpherson), 664
Indicators: Chemical (Prof. O. Tomiček), translated by A. R. Weir, *review*, 641
Indole by *E. coli* · Competitive Action of Isonicotinic Acid Hydrazide and Vitamin B_6 in the Formation of (Masahiko Yoneda, Nobuo Kato and Mitsuharu Okajima), 803
Indole-Acetic Acid · Sensitivity of Cress Roots to (Dr. Franz Moewus and Liselotte Moewus), 372
Indoleacetic Acid Metabolism · Effect of Scopoletin on (W. A. Andreae), 83
3-Indolylacetic Acid · A Synergistic Interaction between 3-Indolylacetonitrile and (Daphne J. Osborne), 210
β-Indolylacetic Acid and Thiourea (Thiocarbamide). A Growth Interaction between (D. Wynn Parry), 1074
3-Indolylacetonitrile and 3-Indolylacetic Acid A Synergistic Interaction between (Daphne J. Osborne), 210
Indoxyl Derivatives. Cytochemical Localization of Esterases using (Dr. S. J. Holt and R. F. J. Withers), 1012
Induction of a Spawning Reflex in Hypophysectomized Killifish (Grace E. Pickford), 807
'Induction Period' in the Preparation of Lithium Aluminium Hydride: Nature of the (Dr. Rafat Mirza), 669
Industrial Leadership and Joint Consultation (Dr. W. H. Scott), 812
Industrial Management in the Welfare State, 811
Industrial Plant in Great Britain: Incentives and Size of (Dr. W. Baldamus), 112
Industrial Research. Secrecy and (Dr. C. E. Kenneth Mees), 972
  Selection, Training and Use of Personnel in (Proceedings of the Second Annual Conference on Industrial Research, June 1951, sponsored by the Department of Industrial Engineering, Columbia University, edited by David B. Hertz and Albert H. Rubenstein), 941
Industrial Research, Virology and Agriculture Fellowships in Natural Science, (British Memorial Fund in Victoria, Australia), 189
Industrial Revolution: Chemistry in the, *review* by W. L. Sumner, 386
Industrial Society (Present-day) The Significance of Information in (Prof. T. U. Matthew), 61; (Aslib Conference), 698
Industries (Nationalized): Organization of, 144
Industry · Application of Science in, 427
  Ash and Clinker in (T. F. Hurley), 999
  British Electronic Instruments in Research and (Scientific Instrument Manufacturer's Association of Great Britain Symposium on), 877
  Human Relations in (Report of the Conference arranged by the Ministry of Labour and National Service), 652
  Scientific and Technical Information for, 827
  Training for (City and Guilds of London Institute Exhibition), 739
Industry (British) Joint Consultation in (Report of an Inquiry undertaken by the National Institute of Industrial Psychology), 255
  Research and Development in the, a Survey of Expenditure on Industrial Research and Development in the Year 1950–51 (Industrial Research Committee of the Federation of British Industries), 465
Industry and Manufacture: The Value and Economic Importance of Chemical Analysis in (Dr. L. H. Lampitt), 599
Industry and Research · The Microscope in (W. Watson and Sons, Ltd., Exhibition on), 348
Influenza Virus Multiplication of, under Conditions of Interference (Dr. S. Fazekas de St. Groth, Dr. A. Isaacs and Miss Margaret Edney), 573
Influenza Virus Haemagglutination. Carbohydrate Residue of a Urine Mucoprotein inhibiting (Dr. Alfred Gottschalk), 662; (Dr. L. Odin), 663
Information for Industry. Scientific and Technical, 827
Information in Present-day Industrial Society The Significance of (Prof. T. U. Matthew), 61; (Aslib Conference), 698
Information Services: Overseas, 633
Information and Broadcasting Services: Overseas (Foreign Office Committee on), 738
'Infra-Red Brooding and the Crooked-Toe Problem in Chicks (Dr. D. J. G. Black, J. Getty and T. R. Morris), 167
Infra-Red Dichroism of Tobacco Mosaic Virus Nucleoprotein (Dr. R. D. B. Fraser), 491
Infra-Red Dichroism and Protein Structure (Dr. R. D. B. Fraser and Dr. W. C. Price), 490
Infra-Red Spectra: Identification of Organic Compounds from (Dr. A. E. Martin), 20
Infra-Red Spectra of Coals (R. R. Gordon, W. N. Adams and G. I. Jenkins), 317

Inhibition (Carbonic Anhydrase) : Inhibition of Gastric Secretion of Hydrochloric Acid *in vivo* by (Henry D. Janowitz, Henry Colcher and Franklin Hollander), 499
Inhibition of Gastric Secretion of Hydrochloric Acid *in vivo* by Carbonic Anhydrase Inhibition (Henry D. Janowitz, Henry Colcher and Franklin Hollander), 499
Inhibition of Lysine Decarboxylase from *E. coli* by Homologous Rabbit Antibody (Arthur F. Howe and Prof. Henry P. Treffers), 123
Inhibition of Œstrus by Cultivated Gromwell (Dr. B. P. Wiesner and Prof. John Yudkin), 274
Inhibition of the Thermal Decomposition of Diethyl Peroxide (A. D. Jenkins and Dr. D. W. G. Style), 706
Inhibitors of Hyaluronidase (L. Hahn), 282
Insect : Name this (Eric Fitch Daglish), *review* by R. D. Moreton, 596
Insect *Hydropsyche angustipennis* (Curtis) (Trichoptera) : Observation of Egg-laying under Water of the Aerial (Ruth M. Baldwin), 40
Insect Flight : Flight-Tone and Wing-Stroke Frequency of Insects and the Dynamics of (Dr. Olavi Sotavalta), 1057
Insect Metamorphosis : Nucleic Acid Metabolism during (Dr. Ivar Agrell), 543
Insect Pests (British) : Common Names of 346
Insect Populations (Lepidoptera) : Use of Radioactive Tracer in the Study of (Dr. H. B. D. Kettlewell), 584
Insect Species : Transmission of Polyhedral Viruses between different (Dr. Kenneth M. Smith and N. Xeros), 492
Insect Trapping : A New Approach to the Problems of the Spread of Aphids and to (Dr. C. G. Johnson), 147
Insecticides (Contact) : Lipoid Solubility as a Factor in the Toxicity of (Dr. S. Pradhan, M. R. G. K. Nair and S. Krishnaswami), 619
Insecticides (Thiophosphate) : Oxidation of, in the Rat (D. K. Myers, Prof. B. Mendel, H. R. Gersmann and Prof. J. A. A. Ketelaar), 805
Insecticides in African Huts : Apparent Fumigant Action of Non-volatile (G. Davidson and G. F. Burnett), 893
Insects : Detection of, by their Carbon Dioxide Production (R. W. Howe and T. A. Oxley) 562
  Flight-Tone and Wing-Stroke Frequency of, and the Dynamics of Insect Flight (Dr. Olavi Sotavalta), 1057
Insects (Social) : Behaviour of, 642
Insignia Award of the City and Guilds of London Institute, 828
Instability : Gravitational, of a Turbulent Medium (Dr. E. N. Parker), 1030
Institute of Metals (Platinum) Medal for 1953 awarded to Prof. Georg Masing, 1098
Instructional Film Research (C. Denis Pegge), 962
Instrumentation (Analytical) : Research in (Dr. R. H. Muller), 599
Instruments (International Astronomical Union Symposium on), 786
Instruments and Measurements (Royal Swedish Academy of Engineering Sciences and the Association of Technical Physicists Conference on), 145
Insulation : Elements of Heat Transfer and (Prof. Max Jakob and Prof. George A. Hawkins), second edition, *review* by D. B. Spalding, 509
Insulation of Electrical Equipment : Vacation School on the (Imperial College of Science and Technology), 1006, 1100
Insulin : Maximum Molecular Weight of (Dr. J. M. Creeth), 210
Insurance : Social, and the Problems of Poverty, 481
Integrity of Science, 379
Intelligence (National) : Level of (Dr. John D. Nisbet), 852
Intensification of the Latent Photographic Image produced by Beta-Rays (Prof. K. Zuber), 669
Intensity Variations of H_α and Effects in Auroral Spectrograms taken in Rapid Succession : Great (Prof. L. Vegard), 536
Interaction between 3-Indolylacetonitrile and 3-Indolylacetic Acid : A Synergistic (Daphne J. Osborne), 210
Interaction of Macromolecules and Fibrinogen (F. Fletcher, L. E. Martin and A. H. Ratcliffe), 319
Interference : Multiplication of Influenza Virus under Conditions of (Dr. S. Fazekas de St. Groth, Dr. A. Isaacs and Miss Margaret Edney), 573
Interference Microspectroscopy (Dr. R. Barer), 29
Interferences of Silk : Relations between Small-Angle, and the Wax Content (Prof. O. Kratky, E. Schauenstein and A. Sekora), 796
Interferometric Techniques : Thin-Film, for High-Magnification Topographical Studies (Prof. S. Tolansky and M. Omar), 81
Interferometry : Silver Films and Dielectric Multiple Films in (Dr. D. A. Jackson and K. Kuhn), 455 ; (Dr. A. H. Jarrett), 456
Interior of the Earth : Temperature of the (Prof. J. A. Jacobs), 838
Intermediates (Organic) : Preparation of (Prof. David Allen Shirley), *review* by J. Idris Jones, 817
Intermetallic Contacts : Surface Oxide Films in (M. Cocks), 203
Internal Fissuring of Wheat due to Weathering (Prof. Max Milner, J. A. Shellenberger, M. R. Lee and Robert Katz), 533
Internal Surface of a Lung : Calculation of the (H. Campbell and Dr. S. L. Tomkeieff), 117
International Conference on the Science and Applications of Photography (Royal Photographic Society), 694
International Conference on Ultrasonics : Proceedings of the (Koninklijke Vlaamse Academie voor Wetenschappen, Letteren en Schone Kunsten van Belgie), 307
International Congress on Astronautics : Third, 348 ; (J. Humphries), 1053
  Proceedings of the Second (edited by L. J. Carter), 486
International Congress of Biochemistry : Second, 443
International Congress on Analytical Chemistry : First, 60, 599
International Congress on Electroacoustics (International Commission on Acoustics of the International Union of Pure and Applied Physics), 1100
International Congress on Medical Librarianship, 564
International Congress on Nutrition : Second, 652
International Congress of Psychology, 145
International Congress on Rheology : Second, 487
International Congress of Therapeutics, 442
International Congress of Zoology : Fourteenth, 784
International Geographical Congress : Seventeenth, 347 ; (Prof. L. Dudley Stamp), 961
  Presidential Address (Dr. George Cressey), 962
International Horticultural Congress : Thirteenth (Royal Horticultural Society), 187 ; (Patrick M. Synge), 647
International Laboratories in Latin America, 605
International Sanitary Regulations (Sir Arthur MacNalty), 1107
International Scientific Relations and National Security, 1033
International Seaweed Symposium (Institute of Seaweed Research, the University of Edinburgh and the Scottish Marine Biological Association), 478
International Symposium on the Chemistry of Cement (Cement and Concrete Association in conjunction with the Building Research Station of the Department of Scientific and Industrial Research), 347 ; (R. W. Nurse), 785
International Symposium on Combustion (Massachusetts Institute of Technology), 60
International Symposium on Desert Research (Research Council of Israel in co-operation with Unesco), 300
1948 International Temperature Scale : To be used by the National Physical Laboratory for Colour Temperatures to Light Sources, 783
Interpretation of Eye-Dominance : Measurement and (Margaret M. Clark), 192
Interpretation of Seismograms : Principles Underlying the (Dr. Frank Neumann), 102
Intertidal Barnacles in relation to the Environment : Changes in the Distribution of the (A. J. Southward and D. J. Crisp), 416
Intestine of Rats with Blind Self-filling Pouch : Absorption from (D. W. Taylor), 81
Intracellular Structures (Isolated) : Use of High Molecular Weight Solutes in the Study of (Dr. John H. McClendon and Prof. L. R. Blinks), 577
Inversion de Walden : Réarrangements moléculaires et (Colloques Internationaux du Centre National de la Recherche Scientifique, 30, Montpellier, Avril 1950), *review* by Prof. J. R. Partington, 944
Invertebrates : The Action of Hormones in Plants and (edited by Kenneth V. Thimann), *review* by Dr. Arthur W. Galston, 724
Iodide (Inorganic) : A Possible Source of Artefacts in the Chromatography of Tissue Extracts containing (J. D. Acland), 32
Iodine-131 : Scintillation Spectrometer Studies on the Decay Schemes of Silver-110, Antimony-124 and (S. Almqvist and Sven A. E. Johansson), 583
Iodine (^{131}I) : British Standard of Radioactive (Dr. E. C. Bullard), 916 ; (Dr. Henry Seligman and John L. Putman), 917
Ion Exchange : Principles and Applications of (Royal Institute of Chemistry, the Chemical Society, the Society of Chemical Industry and the Institute of Petroleum Symposium on), 150
Ion-Exchange Elution Series (Dr. R. C. Vickery), 665
Ionic Equilibrium and Phosphatase Activity : Zinc, (V. Sadasivan), 421
Ionic Impact Phenomena : Electronic and (Prof. H. S. W. Massey and E. H. S. Burhop), *review* by Prof. H. W. B. Skinner, 901
Ionization, pH and Biological Activity (Dr. H. C. S. Wood), 994
Ionization of Bovine Serum Albumin Monolayers (M. Z. Dogan and Dr. J. Glazer), 417
Ionization Loss by Relativistic Particles (Autumn Provincial Meeting of the Physical Society on), 653
Ionizing and Luminous Efficiencies of Meteors (Dr. J. S. Greenhow and Dr. G. S. Hawkins), 355
Ionophoretic Separation of Porphyrin Pigments (Dr. S. C. Papastamatis and Dr. J. E. Kench), 33
Ionosphere : Conductivity of the (Dr. W. G. Baker and Dr. D. F. Martyn), 1090
  Weak Echoes from the, with Radio Waves of Frequency 1·42 Mc./s (S. Gnanalingam and K. Weekes), 113
Ionospheric Phenomenon : A New Early-Morning (B. N. Bhargava), 983
Ions (Complex) : Biological Activity of (Dr. F. P. Dwyer and Dr. Eleonora C. Gyarfas, Dr. W. P. Rogers and Dr. Judith J. Koch), 190
Ions (Metal) (Cr, Al, Fe and Cu) : Tanning of Fatty Acid and Protein Monolayers by (Dr. J. H. Schulman and M. Z. Dogan), 31
Ions (Metallic) : Cellular Permeability of Yeast to (E. Quagliozzi and A. Rescigno), 35, *erratum*, 103
Iraq : Agricultural Census in, 481
Ireland : Sugar Beet Diseases in (Prof. Robert McKay), *review* by W. C. Moore, 469
Iris and its Culture (Jean Stevens), *review* by Dr. H. R. Fletcher, 1037
Iris in the Southern Hemisphere, *review* by Dr. H. R. Fletcher, 1037
Irish Conditions : Molybdenum in relation to Cropping and Livestock Problems under (Dr. T. Walsh, M. Neenan and Dr. L. B. O'Moore), 149
Iron in Podzol Formation : Translocation of (C. Bloomfield), 540
Iron Group of Metals : Thermionic Constants of the (Sir K. S. Krishnan and S. C. Jain), 759
Irons (Cast) : Crystal Distortion of Graphite in (Eitaro Matuyama), 1123
Irradiation of Linear High Polymers (Dr. K. Little), 1075
Irreversible Electrochemical Processes : Thermodynamics of (Peter H. Kemp), 1028
Irreversible Processes : Thermodynamics of (Prof. S. R. de Groot), *review* by H. N. V. Temperley, 89
Isoelectric Point of Chymotrypsinogen by a Donnan Equilibrium Method (Vernon M. Ingram), 250
Isolating Members of the Acrasieae from Soil Samples : A New Method for (E. D. Kitzke), 284
Isolating Plant Cells : Pectinase Technique for (J. Chayen), 1070
Isolation of 11 : 12-Benzfluoranthene from a Coal Tar Fraction (A. S. Harris), 461
Isolation of a Carbamido Acid from Autolysed Yeast (Prof. W. R. Fearon and Dr. W. A. Boggust), 372
Isolation of Phosphothreonine from Bovine Casein (C.-H. de Verdier), 804
Isolation of a Soluble Fibrinolytic Activator from Animal Tissue (Dr. Tage Astrup and Agnete Stage), 929
Isolation of Triploid *Saccharomyces cerevisiae* (Seymour Pomper), 892
Isomeric Forms of Tetraacetyl D-Ribofuranose : An Unusual Transformation of (Dr. John Davoll, George Bosworth Brown and Donald W. Visser), 64
Isomers : Differences in the Biological Activity of 2 : 3 : 5 : 6-Tetrachloronitrobenzene and its (M. Brook), 1022
Isonicotinic Acid Hydrazide and Vitamin B_6 : Competitive Action of, in the Formation of Indole by *E. coli* (Masahiko Yoneda, Nobuo Kato and Mitsuharu Okajima), 803
Isotopes (Radioactive) : Luminescence of Aqueous Solutions of, and the Cerenkov Effect (Dr. E. H. Belcher), 571
  Technique of handling and using (Course of Instruction at the Ministry of Supply's Isotope School at Harwell), 694
Isotopes in Medicine (Dr. L. F. Lamerton), 350
Israel : Bi-Lingual Guide to the Inter-Library Microfilm Catalogue of the Scientific Libraries in (Research Council of Israel), 694

JAPANESE Researches in Biophysics, 482
Jelly-like Materials ? Deposition of Metal Films on (Edwin Rosenstiel), 85
Jodrell Bank Annals, a New Astronomical Journal, 188
Johnson Matthey Silver Medal of the Institute of Metal Finishing endowed by Johnson Matthey and Co , Ltd., 229
Joint Consultation : Industrial Leadership and (Dr W. H. Scott), 812
Journal of Botany : *The Annals and Magazine of Natural History* to combine with the, 405
Journal of the Mechanics and Physics of Solids : Vol. I, No. 1, 955
Journal of the Royal Society of Arts : Centenary Number of the, 1048
Journal of Scientific Instruments (edited by Dr H. R Lang), Vol. 28 and Supplement No. 1, 1951, *review* by S. Weintroub, 298, *erratum*, 784
Judée : Le paléolithique et le mésolithique du Désert de (René Neuville), *review* by M C. Burkitt, 386
Judgment . Some Factors affecting Choice and (British Association for the Advancement of Science Symposium on), 555
Jungfraujoch : Twenty Years of Work at the (M. D. Chalonge), 186
Jute : Viscosity of Sodium Salt of Polyuronide Hemicellulose from (Dr. P. K. Saha), 281
Jute (*Corchorus capsularis*) · Origin and Development of Axillary Buds in (Dr. B. C. Kundu and N. S. Rao), 1128
Jute (*Corchorus olitorius* Linn.) : *Nupserha bicolor* Thoms., subsp *postbrunnea* Breun., a New Pest on (N. Dutt), 287
Jute Seeds (*Corchorus capsularis*, Linn.) : Corchsularin, a New Bitter Principle from (M. A. Khalique and M. Ahmed), 1019
Juveniles : Christmas Lectures in London for, 829

K-REGION Hypothesis of Carcinogenic Chemical Compounds . Extension of the (E C. Kooyman and J. W. Heringa), 661
Kamchatka · Earthquake near, 914
Kashmir . Breeding Birds of (Lieut.-Colonel R. S. P. Bates and E. H. N. Lowther), *review*, 511
Kelvin Premium of the Institution of Electrical Engineers awarded to Dr. A. L Cullen, 19
Keratin · Reversal of the Molecular Set in (J. Sikorski), 273
α-Keratin a Coiled Coil ? · Is (F. H. C. Crick), 882
Keratin and Collagen : The Reactivity of Protein Fibres—some Analogies between (Prof. J. B. Speakman), 1054
Ketone-Body Excretion : A Substance in Animal Tissues which stimulates (H. B. Stewart and Prof. F. G. Young), 976
Ketones (Volatile Aldehydes and) . Separation of the 2,4-Dinitrophenylhydrazones of, by Paper Chromatography (Dr. D. F Meigh), 579
Ketones (Unsaturated) · Peroxidation of (Dr. Ernest Wenkert and Mordecai Rubin), 708
Ketose Sugars · An Extended Orcinol Test Specific for (J. Howarth Williams), 894
Ketosis (Ovine) : Acetate Metabolism in (P. Storie Pugh and R. Scarisbrick), 978
Killifish (Hypophysectomized) · Induction of a Spawning Reflex in (Grace E. Pickford), 807
Kinetics . Chemical (Prof. Keith J. Laidler), *review* by J. R. P., 817
Kinetics (Reaction) · Stabilization of Free Radicals, its Importance in (Prof. Zoltán G. Szabó), 246
Knowledge : Harnessing—Annual Conference of Aslib, 698

LABORATORIES (British) American Scientific Equipment for, 566
Laboratories in Latin America International 605
Laboratory Techniques in the Testing of Milk, *review* by J. King, 683
Lactic Oxidases of *Mycobacterium tuberculosis avium* (Yuichi Yamamura, Masamiti Kusunose and Emi Kusunose), 207
Lactobacilli : Possible Identity of 'Lactobacillin' with Hydrogen Peroxide produced by (Dorothy M. Wheater, Dr. A. Hirsch and Dr. A T. R. Mattick), 623
'Lactobacillin' : Possible Identity of, with Hydrogen Peroxide produced by Lactobacilli (Dorothy M. Wheater, Dr. A. Hirsch and Dr. A. T. R. Mattick), 623
Lacto-bionate : Microbiological Decomposition of Malto- and (M. Bernaerts and Dr. J. De Ley), 713
Lamellibranchia : Shell-form in the (G. Owen), 148
Land for Agriculture : Reclaiming (Moses Griffith, J. F. H. Thomas and R. Line), *review* by G V Jacks, 858
Land for 2·4 Billion Neighbors (Dr. George Cressey), 962
Land Reclamation, *review* by G V Jacks, 858
Land Reform—Defects in Agrarian Structure as Obstacles to Economic Development (United Nations Department of Economic Affairs Report on), 102
Land Reform in Under-developed Countries · Problems of, 102
Landwirtschaftliche Zwischennutzung im Walde als Meliorationsmittel und Hilfe fur die Ernahrung (W. Wittich) 562
Lanostenol Structure of (R. G. Curtis, J Fridrichsons and A. McL. Mathieson), 321
Larvæ (*Simuliidae*) : Fish Feeding on (Dr. G. Marlier), 496
Latent Photographic Image produced by Beta-Rays : Intensification of the (Prof. K. Zuber), 669
Laterite and Lateritic Soils (J. A. Prescott and R. L. Pendleton), 871
Lateritic Soils · Laterite and (J. A. Prescott and R. L. Pendleton), 871
Latex '580G' (Dow) · Resuspension of, by Ultrasonics (P. Hatfield, H. W. Emerton and P. E Wrist), 797
Lathyrus sativus : Toxic Principle of (Prof. M. N. Rudra), 124
Latin America · International Laboratories in, 605
  Science in, 306
  Scientific Institutions and Scientists in (Unesco Science Co-operation Office for Latin America), Venezuela, Vol. 1, 306 ; Brazil, Vol. 3, 306
Latin American Contributions to Scientific Progress—Chemistry, 1948–49 (Unesco Science Co-operation Office for Latin America), 306
Latitudes (Lower) : Enhancement of Auroral Hydrogen Lines towards (Prof. L. Vegard), 1120
Lattice Vacancies and Porosity in Copper–Nickel Alloys (Dr. E. C. Ellwood), 580
Laurentian Hormone Conference : Proceedings of the (Recent Progress in Hormone Research, Vol. 5, edited by Gregory Pincus), *review*, 858
Law : Smoke and the (W. R. Hornby Steer), 484
Law of Patents : Terrell and Shelley on the, ninth edition, by K. E. Shelley, *review* by R. G. Lloyd, 49
Leaf Form in *Callitriche intermedia* : Variation in (Herbert Jones), 848
Leaves : Abnormal, of *Cycas revoluta* Thumb. (Ramesh Kumar Srivastava), 253
  Proline and Hydroxyproline in (Prof. K. V. Giri, K. S. Gopalkrishnan, A. N. Radhakrishnan and C. S. Vaidyanathan), 579
Leaves of *Drosera capensis* L. : Transport of Substances through the Tentacles of (Prof. W. H. Arisz), 932
Leaves, Roots and Root Nodules of the Alder (*Alnus*) : Free Amino-Acids in the (Prof. Artturi I. Virtanen and Jorma K. Miettinen), 283
Lectures or Research in the Universities of the United States Grants to British Scholars for (American Embassy and the United States Educational Commission in the United Kingdom), 145
Leeuwenhoek Lecture of the Royal Society (Prof. A. J. Kluyver), 829
Legumes : Amino-acids in (Dr. N. G. Baptist), 76
Leguminous Root-Nodules . Carbohydrate Fermentation of Bacterial Isolates from Zygophyllaceous and (Prof. M. A. Mostafa), 276
Lemna minor : Effects of Preliminary Treatment on the Subsequent Variation in the Resistance of, to the Phytotoxic Action of 2 · 4 Dichlorophenoxyacetic Acid (R. C. Robertson-Cuninghame and Prof. G. E. Blackman), 459
  Some Effects of Ultra-violet Radiation on (Dr. E. Wangermann and H. J. Lacey), 126
Lens Making : Prism and (F. Twyman), second edition, *review* by H. W. Lee, 553
Leopard Seal : Observations on the Newly Born (K. G. Brown), 982
Lepine and Sautter's Disease in Great Britain (Dr. R. Hadek), 165
Leptospira icterohaemorrhagiae : Toxicity of Methylene Blue to (J. J. Lawrence), 327
Less-Developed Areas : Enquiries into Household Standards of Living in (United Nations Department of Social Affairs), 529
D(+)-Leucine : Effect of, on the Hydrolysis of Glycyl-L-Leucine in Normal and Neoplastic Tissues (Prof. A. Vescia, A. Albano and A. Iacono), 804
Librarianship (Medical) · International Congress on, 564
Libraries · Newspaper (J. Lewis), 563
Library (Special) The Development and Administration of a (C. H. Tomalin), 956
Library Services in the British Colonial Territories (Lionel R. McColvin), 169
Libyan Desert Silica-Glass Dating the (Dr. Kenneth P. Oakley), 447
Life : The Bridge of—from Reality to Mystery (Dr. Augusto Pi Suñer), *review* by N. W. Pirie, 92
  The Conduct of (Lewis Mumford), *review* by R. Brightman, 1085
  World Congress of Medical Practitioners for the Study of the Actual Conditions of, 739
Life in Less-Developed Areas : Standards of, 529
Life of the Western Atlantic Coast, *review* by Dr. D. P. Wilson, 640
Light : Decay of, to Very Low Levels from Spark Discharges (R. H. Johnson and D. E. H. Jones), 669
Light (Intermittent White) : Retinal Colour Processes caused by (Prof. Koiti Motokawa and Mitsuru Ebe), 79
Light at the National Physical Laboratory : Standards of, 405
Light Nuclei · Some Investigations of (Dr. C. C. Lauritsen), 612
Light-Profile Microscope . Evaluation of Small Radii of Curvature using the (Prof. S Tolansky and M. Omar), 758
Light-scattering Method Molecular Weight of Glycogens determined by a (B. S. Harrap and D. J. Manners), 419
Light Waves : Adventures with Standing (Prof. H. E. Ives), 1111
Lightning · Franklin's 'Philadelphia Experiment' on, 1099
  Radio Echoes and (V G. Miles), 365
Lignin The Chemistry of (Friedrich Emil Brauns), *review* by Dr. Julius Grant, 338
Lignin and Wood : Chemistry of, *review* by Dr. Julius Grant, 338
Lilly (Eli) Travelling Fellowships in Medicine (Medical Research Council Awards), 189
Limes (Magnesian) · A Method for Overcoming 'Unsoundness' in (T. Demediuk), 799
Lingula : Giant Nerve Cells in (P. Kirtisinghe), 206
Linkage : A New, in the House Mouse—Vestigial and Rex (Donald Michie), 585
Linkage in Micro-organisms : Competitive Suppression and the Determination of (J. L. Jinks), 106
Linnaeus Redivivus, *review* by Prof. F. J. Cole, 1036
Linnean Tradition in Sweden, 872
Lipid Material ('Cord Factor') : Purification of a, obtained from Young Cultures of Tubercle Bacilli (E. Sorkin, H. Erlenmeyer and H. Bloch), 124
Lipids · The (Prof. Harry J. Deuel, Jr.), Vol. I, Chemistry, *review* by Dr. F. D. Gunstone, 727
'Lipochondria' and the Golgi Substance in Epithelial Cells of the Epididymis (A. J. Dalton and Marie D. Felix), 541
Lipoid Solubility as a Factor in the Toxicity of Contact Insecticides (Dr. S. Pradhan, M. R. G. K. Nair and S. Krishnaswami), 619
Lipoprotein Precursor of Sclerotin in the Cockroach Cuticle (S. R. A. Malek), 850
Liquid Argon . Viscosity and Thermal Conductivity of (Prof. E. N. da C. Andrade), 794
Liquids : Direct Calculation of Viscosities of (M. S. Telang), 160
  Miscibility of, influenced by Rate of Shear (A. Silberberg and Prof W. Kuhn), 450
Literature : Current, relating to Scientific Instruments, 1001
Lithium Aluminium Hydride Nature of the 'Induction Period' in the Preparation of (Dr. Rafat Mirza), 669
  Reduction of Tropinone with (Dr. Rafat Mirza), 630
Liver (Rat) : Glucose-6-Phosphate Dehydrogenase Activity of (Dr. G. E. Glock and P. McLean), 119
Liver Fractions : Formation and Breakdown of Pentose Phosphates by (Dr. Gertrude E. Glock), 162
Liver Vitamin A Reserves : Lowered, in Avian Coccidiosis (Alan W. Davies), 849
Livestock : A World Dictionary of Breeds, Types and Varieties of (I. L. Mason), *review* by Dr. John Hammond, 260
Livestock Problems under Irish Conditions : Molybdenum in relation to Cropping and (Dr. T. Walsh, M. Neenan and Dr. L. B. O'Moore), 149

Living : Experiments in, a Study of the Nature and Foundation of Ethics or Morals in the Light of Recent Work in Social Anthropology (Prof A Macbeath), *review* by Lord Raglan, 174
Living in Less-Developed Areas : Enquiries into Household Standards of (United Nations Department of Social Affairs) 529
Living Tide · The (Prof. N. J. Berrill), *review* by Dr. D. P. Wilson, 640
Local Government : National Parks and, 333
Local Scientific Societies—Problems and Responsibilities (J. A. S Stendall), 401
Locust · Nerve Impulses originating from the Compound Eye of the (E. T. Burtt and W. T. Catton), 285
Locusta : Abdominal Mechano-Receptors in *Dytiscus* and (G. M Hughes), 531
Lodestone · An Elizabethan (Loaned by Lord Wharton to the National Maritime Museum, Greenwich), 562
Logical Foundations of Probability (Prof. Rudolf Carnap), review by Prof. Harold Jeffreys, 507
London : A Commonwealth Institute in, 899
  A Survey of Cancer in (Dr. W. L. Harnett), *review* by Dr. I. Doniach, 220
London during 1938–39 : Survey of Cancer in, *review* by Dr I Doniach, 220
London Pond : Trematode Life-Cycle enacted in a (Dr. Ben Dawes), 72
Loranthaceae : Root Parasites in (H S McKee), 40
Lotmar-Picken Material from Dried Muscle : Extractability of the (Dr. H E. Huxley and Dr. J. C. Kendrew), 882
Low-Energy Primary Cosmic Radiation . Apparent Absence of (E. G Dymond) 1078
Low Temperature Physics (F. E. Simon, N. Kurti, J. F. Allen, K. Mendelssohn), *review* by S Weintroub, 1088
Lower Devonian Charophyte (W. N Croft), 1002
Lumbricus terrestris L : Extrusion of Nucleolar Material in the Female Germ-Cells of (D. S. Srivastava), 757
Luminescence of Aqueous Solutions of Radioactive Isotopes and the Cerenkov Effect (Dr E H. Belcher), 571
Luminescence of Solids : An Introduction to (Humboldt W. Leverenz), *review* by Dr E. J Bowen, 259
Luminous Efficiencies of Meteors : Ionizing and (Dr. J S. Greenhow and Dr. G. S. Hawkins), 355
Lung . Calculation of the Internal Surface of a (H. Campbell and Dr S. I. Tomkeieff), 117
Lupin · Secondary Piliferous Layer in the (Miss P. A. Lush), 127
Lyell Fund (a moiety of the) for 1953 of the Geological Society awarded to Dr. Gilbert Wilson and to Dr. D. A. Brown, 1098
Lyell Medal for 1953 of the Geological Society of London awarded to Dr. M. B Bulman, 1098
Lyophobic Sols : Stability of (Dr. V. B. Vouk), 762
Lysenko's Latest Discovery—The Conversion of Wheat into Rye, Barley and Oats (Prof. P Maheshwari), 66
Lysine Decarboxylase from *E. coli* . Inhibition of, by Homologous Rabbit Antibody (Arthur F Howe and Prof. Henry P. Treffers), 123
Lysozyme · Cell Wall of *Micrococcus lysodeikticus* as the Substrate of (M. R. J. Salton), 746

MCMICHAEL (Leslie) Premium of the British Institution of Radio Engineers awarded to R G Kitchenn, 308
Macromolecules · Biologically Significant (British Association for the Advancement of Science, Section B (Chemistry), Discussion on), 690
Macromolecules and Fibrinogen : Interaction of (F. Fletcher, L. E. Martin and A. H. Ratcliffe), 319
Macrophages in the Periodontal Tissues of Rats' Incisor Teeth (Prof. J. T. Irving), 573
Magnesian Limes . A Method for Overcoming 'Unsoundness' in (T. Demediuk), 799
Magnesium (Gmelins Handbuch der anorganischen Chemie, achte Auflage, System-Nummer 27, Teil A, Lieferung 4), *review* 902
Magnesium Requirements . Minimum Phosphate and, of Nitrifying Bacteria (Dr. Jane Meiklejohn), 1131
Magnetic Properties, Internal Strains and the Bauschinger Effect in Metals (D V Wilson), 30
Magnetic Storms and Aurorae . Theories of (Dr. J. W. Dungey), 795
Magnetic Susceptibilities of Palladium–Rhodium Alloys from 20° to 300° K (Dr. F. E. Hoare, J S. Kouvelites and J. C. Matthews), 537
Magnetic Susceptibility of an Oxygen Clathrate Compound : Preparation and (D. F. Evans and Dr R. E. Richards), 246
Magnetostrictive Effect and the Δ-*E* Effect in Nickel (Henrik Nördvedt), 884
Maize Embryos (Excised) · Effect of Tissue Cultures of Maize Endosperm on the Growth of (Elizabeth A Pieczur), 241
Maize Endosperm : Effect of Tissue Cultures of, on the Growth of Excised Maize Embryos (Elizabeth A Pieczur), 241
Malarial Infections : 'Daraprim' Resistance in Experimental (I. M. Rollo), 415
Malaya . Pharmacological and Toxicological Actions of Dart Poison used in (Robert Chun Yu Lin), 416
Malayan Forest Rats : Moonlight and the Pregnancy of (J. L Harrison), 73
Malaysia : History of Botanical Exploration in, *review* by H. S Marshall, 336
Male Sterile Plants by Chemical Treatment (Dr. S. Rehm), 38
Malesiana : Flora (general editor, Dr. C. G. G. J. van Steenis), Series I, Spermatophyta, Vol. I, Malaysian Plant Collectors and Collections (Mrs M. J. van Steenis-Kruseman), *review* by H. S. Marshall, 336
Malnutrition in Tropical Africa . Conference on (Commission for Technical Co-operation in Africa South of the Sahara), 872
Malonic Acid in Plants · Occurrence of (Miss L. E. Bentley), 847
Malto- and Lacto-bionate : Microbiological Decomposition of (M. Bernaerts and Dr J. De Ley), 713
Mammalian Sperm : The 'Capacitation' of (C. R. Austin), 326
  Chemical Composition of (R. Duncan Dallam and Prof. Lloyd E. Thomas), 377
Mammals :– Foetal Fructose in various (R. F. W. Goodwin), 750
  Passage of the Sperm and the Penetration of the Egg in (C. R. Austin and A. W. H. Braden), 919
Mammals (British) . A List of (T. C. S. Morrison-Scott), 188
Mammals (Palaearctic and Indian) : Checklist of, 1758 to 1946 (J R. Ellerman and T C. S. Morrison-Scott), *review* by Dr. L. Harrison Matthews, 298
Mammals of the Old World, *review* by Dr. L. Harrison Matthews, 298
Man : Energy in the Service of (Unesco Discussion on), 611
  The Molds and (Prof. Clyde M. Christensen), *review* by Dr. J. Grainger, 1088
Man (Christian) : Science and the (Cannon Charles E. Raven), *review* by Dr. F. Sherwood Taylor, 473
Man (Modern) : A Philosophy for, *review* by R. Brightman, 1085
Man-power in Scientific Research and Development, 505
Man-power Problems . Scientific Research and, 129
Management . Ethics of (H E. Roff), 102
  Joint Consultation in, 255
  A Philosophy of, *review* by E F. L. Brech, 430
Management in Scotland (T. H. Hawkins), 65
Manby Premium of the Institution of Civil Engineers awarded jointly to Dr. B. G. Neal and Dr. P. S Symonds, 870
Manchester Pharmaceutical Association Scholarship of the Pharmaceutical Society awarded to R. A. Alcock, 346
Manson Lectures for 1952 of the Royal Institute of Philosophy, 608
Manufacture : The Value and Economic Importance of Chemical Analysis in Industry and (Dr L. H. Lampitt), 599
Manx Waters · *Pelagia* in (Prof. F. J. Cole), 587
Map Measure (J. E Buck and Co), 484
Marconi Premium of the British Institution of Radio Engineers awarded to E. G. Rowe, 308
Marine Biology in Scotland, 311
Marine Engineering : Scholarships in Naval Architecture and (Institution of Naval Architects), 1049
'Marsh Factor' . Effect of the, on the Shortening of Muscle Fibre Models in the Presence of Adenosine Triphosphate (J. R. Bendall), 1058
Mass . Introduction to the Transfer of Heat and (E. R. G. Eckert), *review* by D. B. Spalding, 1089
Materiae Vegetabiles, No 1, 956
Material in Filter Paper Chromatography · Application of (Prof. U S. von Euler and R Eliasson), 664
Materials · Plasticity of (British Society of Rheology Conference on), 875
Mathematical Biology of Social Behavior (Nicolas Rashevsky), *review* by E. Grebenik, 3
Mathematical Sociology ?, *review* by E. Grebenik, 3
Mathematical Tables · Advanced Five-Figure (C Attwood), *review* by J. H Pearce, 641
Mathematics (Applied) : Survey of, in the United States (United States National Academy of Sciences), 872
Mathematics of Experimentation, *review* by Dr. D. J Finney, 991
Mather Premium of the Institution of Electrical Engineers awarded to D F. Lawden, 19
Mating Behaviour of the Ewe : Role of Progesterone in the (T. J. Robinson), 373
Maxwell (Clerk) Premium of the British Institution of Radio Engineers awarded to Dr. H. Paul Williams, 308
Measurement and Importance of Elastic Properties of Metals (Conference at the National Physical Laboratory, Teddington), 527
Measurement and Interpretation of Eye-Dominance (Margaret M. Clark), 192
Measurements · Instruments and (Royal Swedish Academy of Engineering Sciences and the Association of Technical Physicists Conference on), 145
  Thermal, on Small Transient Systems (R. A. W. Hill), 29
Measures in Great Britain : Weights and, 1001
Measuring Potential Evapotranspiration : A Simple Apparatus for (Prof B J. Garnier), 286
Measuring and Grading Microscopic Spherical Particles · A Method of (Dr. V. Timbrell), 318
Mécanisme de l'oxydation : Rapports et discussions (Institut International de Chimie Solvay, Huitième Conseil de Chimie tenu à l'Université de Bruxelles, Septembre 1950), *review by Prof.* J. R. Partington, 944
Mechanical Engineering in Manchester, 953
Mechanics and Physics of Solids, Journal of the : Vol I, No. 1, 955
Mechanism of Fracture of Concrete (Dr Frank A. Blakey), 1120
Mechano-Receptors in *Dytiscus* and *Locusta* : Abdominal (G M. Hughes), 531
Media : Salting-out Chromatography of Amino-acids and Peptides in Filter Paper and other (L. Hagdahl and Prof. A. Tiselius), 799
Medical Importance : Polysaccharides of (Prof. M. Stacey), 690
Medical Librarianship : International Congress on, 564
Medical Protozoology in the University of London, 100
Medical Science : French Exchange Scholarships in (Medical Research Council Awards), 189
Medical and Scientific Periodicals (German) · Cost of (Dr. W. Bonser and Margaret P. Russell), 446
Medicinal Chemistry (Prof. Alfred Burger), Vol. 2, *review* by Prof J. W. Cook, 1086
Medicine : The Contribution of, to our Idea of the Mind (Sir Russell Brain), 58
  Eli Lilly Travelling Fellowships in (Medical Research Council Awards), 189
  Isotopes in (Dr. L F. Lamerton), 350
  Primitive, at the Wellcome Historical Museum, 273
  Rockefeller Travelling Fellowships in (Medical Research Council Awards), 189
Medicine of the Aboriginal Peoples in the British Commonwealth : Catalogue of an Exhibition illustrating the (Wellcome Historical Medical Museum), 273
Mediterranean Countries · Pasture and Fodder Development in (Prof N. M. Comber), 56
Medium-Energy Nuclear Physics (University of Pittsburgh Conference on), 349
Melanins · Solubility of (A. J. Lea), 709
Melchett Medal for 1953 of the Institute of Fuel awarded to Dr. H. Hartley, 1047
Meldola Medal of the Society of Maccabaeans for 1953, 739
Melting Ferromagnetic Semiconductors : A New Method of—$BaFe_{12}O_{19}$, a New Kind of Ferromagnetic Crystal with High Crystal Anisotropy (H P. J. Wijn), 707
Meniscus between Water and Organic Solvents : Flattening of (Dr. A. F. H Ward and L. H Brooks), 118
Mental Epidemiology, *review* by Prof John Cohen, 472

Merck Fellowships of the National Research Council, Ottawa, 189
Mercury Dimethyl, Diethyl and Diphenyl and some Associated Bond Dissociation Energies : Heats of Formation of (A. S. Carson, Mrs. E. M. Carson and B. Wilmshurst), 320
Mesenteric Ganglion : Excitation of Ganglion Cells in the Inferior, by Collaterals (C. Job and Dr. A. Lundberg), 205
Mésolithique du Désert de Judée : Le paléolithique et le (René Neuville), *review* by M. C. Burkitt, 386
Mesomorphism of *p*-*n*-Alkoxybenzoic and 6-*n*-Alkoxy-2-Naphthoic Acids : Influence of Substituents on the (G. W. Gray and Prof. Brynmor Jones), 451
τ-Meson : Observations of a (M. Ceccarelli, Prof. N. Dallaporta, M. Merlin and A. Rostagni), 454
π^0-Meson : The, 513
Meson Masses (Dr. K. M. Guggenheimer), 158
Messel Memorial Lecture of the Society of Chemical Industry (Sir Henry Tizard), 427
Metabolism : Acetate, in Ovine Ketosis (P. Stone Pugh and R. Scarisbrick), 978
Metabolism (Creatine) : A Sparing Effect by Formate or Methanol on the Impairment of, in Folic Acid Deficiency (Prema Fatterpaker, Urmila Marfatia and Dr. A. Sreenivasan) 894
Metabolism (Indoleacetic Acid) : Effect of Scopoletin on (W. A. Andreae), 83
Metabolism in Higher Plants : Anatomy of (Prof. Meirion Thomas), 399
Metabolism during Insect Metamorphosis : Nucleic Acid (Dr. Ivar Agrell), 543
Metabolism of Micro-organisms (Symposium on, at the Second International Congress of Biochemistry), 444
Metabolism by Soil Bacteria of Benzoyl Derivatives of D- and L-Forms of some Amino-acids : Hydrolysis and (Prof. Yukio Kameda, Etsuko Toyoura, Hiroshi Yamizoe, Yukio Kimura and Yoshiro Yasuda), 888
Metal Bodies (Porous) : Determination of the Pore-Size Distribution in (Dr. P. R. Marshall), 761
Metal Films (Evaporated) : Russell Effect on (L. Grunberg and K. H. R. Wright), 456
Metal Films on Jelly-like Materials : Deposition of (Edwin Rosenstiel), 85
Metal Ions (Cr, Al, Fe and Cu): Tanning of Fatty Acid and Protein Monolayers by (Dr. J. H. Schulman and M. Z. Dogan), 31
Metal Surfaces : Autoradiography of, using a Radiochemical Method (E. Rabinowicz), 1029
Metal-Tropolone Complexes : Formation Constants of some (Burl E. Bryant, Prof. W. Conard Fernelius and Bodie E. Douglas), 247
Metallic Ions : Cellular Permeability of Yeast to (E. Quagliozzi and A. Rescigno), 35, *erratum*, 103
Metallic Surfaces : Properties of (Institute of Metals Symposium on), 442
Metallurgy (Powder) : Treatise on (Dr. Claus G. Goetzel), Vol. 3, *review* by H. W. Greenwood, 817
Metallurgists : Education and Training of (Prof. F. C. Thompson), 182
  Education and Training of, 989
Metals : Demonstration by Radioactive Tracers of the Adsorption of Cations by (Prof. J. Palacios and A. Baptista), 665
  The Hardness of (D. Tabor), *review* by Prof. A. G. Quarrell, 818
  Magnetic Properties, Internal Strains and the Bauschinger Effect in (D. V. Wilson), 30
  Measurement and Importance of Elastic Properties of (Conference at the National Physical Laboratory, Teddington), 527
  Principles of the Extraction and Refining of (Institution of Metallurgists), 405
  Thermionic Constants of the Iron Group of (Sir K. S. Krishnan and S. C. Jain), 759
Metals (Trace) : Time and, in Archæological Sites (V. P. Sokoloff and G. F. Carter), 872
Metamorphosis (Insect) : Nucleic Acid Metabolism during (Dr. Ivar Agrell), 543
Meteor Train (Dr. A. R. Hogg), 305
Meteorites and Cosmic Rays (Dr. S. F. Singer), 728 ; (Prof. F. A. Paneth), 729
Meteorological Changes in the Period January–April 1949 : Geophysical and (R. P. Waldo Lewis and D. H. McIntosh), 488
Meteorological Tables : Smithsonian (prepared by Robert J. List), sixth revised edition, *review* by G. A. Bull, 175
Meteorology : Application of Radar to—Conference in Montreal (R. F. Jones), 1004
  Compendium of (edited by Thomas F. Malone), *review*, 814
  Present Position of, *review*, 814
Meteorology in the University of London, 15
Meteorology and Agriculture (Sir Robert Watson-Watt), 738
Meteors : Ionizing and Luminous Efficiencies of (Dr. J. S. Greenhow and Dr. G. S. Hawkins), 355
Meteors (Sporadic) : Velocity Distribution of (Mary Almond, J. G. Davies and A. C. B. Lovell), 872
Methane Fermentation in the Rumen of Cattle (W. H. Beijer), 576
Methane and Coal (Sir Alfred Egerton), 93
Methanol : A Sparing Effect by Formate or, on the Impairment of Creatine Metabolism in Folic Acid Deficiency (Prema Fatterpaker, Urmila Marfatia and Dr. A. Sreenivasan), 894
Methylene Blue : Toxicity of, to *Leptospira icterohaemorrhagiae* (J. J. Lawrence), 327
Mice : Terramycin in the Treatment of Experimental Rabies in (M. A. Haseeb), 983
Michelson-Morley Experiment : Gardner's Hypothesis and the (Prof. J. L. Synge), 243
Microbe : The Changing Appraisal of the (Prof. A. J. Kluyver), 829
Microbial Decomposition of Cellulose (R. G. H. Siu), *review*, 594
Microbiological Decomposition of Malto- and Lacto-bionate (M. Bernaerts and Dr. J. De Ley), 713
Micrococcus lysodeikticus : Cell Wall of, as the Substrate of Lysozyme (M. R. J. Salton), 745
Microdiffusion Analysis and Volumetric Error (Prof. Edward J. Conway), third edition, *review* by A. L. Bacharach, 5
Microfilm Catalogue of the Scientific Libraries in Israel : Bi-Lingual Guide to the Inter-Library (Research Council of Israel), 694
Micro-forceps and Micro-scalpels (J. Worst), 1129
Micro-Magnetic Variations during the Solar Eclipse of February 25, 1952 (Prof. N. F. Astbury), 68
Micro-organisms : Competitive Suppression and the Determination of Linkage in (J. L. Jinks), 106
  Metabolism of (Symposium on, at the Second International Congress of Biochemistry), 444
Microradiography with Alpha-Rays (Gunnar Anlansson and Naftali Steiger), 201
Micro-scalpels : Micro-forceps and (J. Worst), 1129
Microscope : The Flying-Spot (F. Roberts and Prof. J. Z. Young), 137
Microscope (Flying-Spot) : High-Speed Counting with the (F. Roberts and Prof. J. Z. Young), *erratum*, 19
Microscope (Light-Profile) : Evaluation of Small Radii of Curvature using the (Prof. S. Tolansky and M. Omar), 758
Microscope in Industry and Research (W. Watson and Sons, Ltd., Exhibition on), 348
Microscope Objective (Ultra-Violet) : An Easily Used (Dr. M. H. F. Wilkins and K. P. Norris), 883
Microscopy : Diffraction, with X-Rays (M. E. Haine and T. Mulvey), 202
  X-Ray Shadow (Dr. V. E. Cosslett and Dr. W. C. Nixon), 436
Microscopy (Direct Fluorescence) : Counting Soil Algæ by (Y. T. Tchan), 328
Microspectroscopy : Interference (Dr. R. Barer), 29
Micro-spherical Aggregation of Barium Sulphate (D. L. Stock), 423, *erratum*, 484
Microwave Vibration Wattmeter (Dr. A. L. Cullen), 1121
Middle East : Citrus Entomology in the (F. S. Bodenheimer), *review* by Prof. H. C. Efflatoun, 218
  Scientific Papers published in the (Unesco Middle East Science Co-operation Office), List No. 6, 346
Migration and Gregarious Æstivation in the Bogong Moth, *Agrotis infusa* (I. F. B. Common), 981
Mild Conditions : Colorimetric Determination of Formaldehyde under (T. Nash), 976
Milk : Laboratory Techniques in the Testing of, *review* by J. King, 683
Milk Testing (Dr. J. G. Davis), *review* by J. King, 683
Million Years : The Next (Sir Charles Galton Darwin), *review* by Sir John Russell, 636
Mind : The Contribution of Medicine to our Idea of the (Sir Russell Brain), 58
  Temporal Integration as a Clue to, *review* by Dr. John Cohen, 297
Mind and its Place in Nature (Manson Lectures for 1952 of the Royal Institute of Philosophy), 608
Mineral Dressing (Institution of Mining and Metallurgy Symposium on), 699
  Application of Radioactivity to (Prof. A. M. Gaudin), 656
Mineral Nutrition : Influence of, on the Resin Content of the Hop Cone (F. C. Thompson and Dr. A. H. Burgess), 890
Mineral Nutrition of Plants (edited by Emil Truog), *review* by Dr. G. Bond, 176
Mineralogy at the British Museum (Natural History), 1000
Minerals : Clay, *review* by Dr. F. A. Bannister, 337
Minerals (Clay) : X-Ray Identification and Crystal Structures of (edited by G. W. Brindley), *review* by Dr. F. A. Bannister, 337
Mining and Metallurgical Congress : Fifth Empire, 563
Minnow : Influence of Thiourea on Reproduction in the (Prof. E. J. W. Barrington and A. J. Matty), 105
Miscibility of Liquids influenced by Rate of Shear (A. Silberberg and Prof. W. Kuhn), 450
Mississippi : A Guide to Bird Finding East of the (Olin Sewall Pettingill, Jr.), *review*, 52
Mitosis : Physiology of, *review* by Prof. W. S. Bullough, 51
Mitotic Crossing-over : Non-random Distribution of Multiple, among Nuclei of Heterozygous Diploid *Aspergillus* (Dr. G. Pontecorvo), 204
Mitotic Cycle : The (Dr. Arthur Hughes), *review* by Prof. W. S. Bullough, 51
Moisture Relations and Textile Fibres (British Association for the Advancement of Science, Section A (Mathematics and Physics), Discussion on), 732
Moisture-content : Natural, Porosity and Compaction of Clayey Deposits (Prof. P. G. H. Boswell), 156
Molds and Man (Prof. Clyde M. Christensen), *review* by Dr. J. Grainger, 1088
Molecular Dynamics : Molecular Spectra and, *review* by Dr. H. W. Thompson, 469
Molecular Set in Keratin : Reversal of the (J. Sikorski), 275
Molecular Size : Reduction of Nitrophenanthridinium Salts—Influence of, on Trypanocidal Activity (Dr. L. P. Walls and E. Beveridge), 666
Molecular Spectra and Molecular Dynamics, *review* by Dr. H. W. Thompson, 469
Molecular Spectra and Molecular Structure (Gerhard Herzberg), 1, Spectra of Diatomic Molecules, second edition, *review* by Dr. H. W. Thompson, 469
Molecular Structure : Molecular Spectra and (Gerhard Herzberg), 1, Spectra of Diatomic Molecules, second edition, *review* by Dr. H. W. Thompson, 469
Molecular Weight of Glycogens determined by a Light-scattering Method (B. S. Harrap and D. J. Manners), 419
Molecular Weight of Insulin : Maximum (Dr. J. M. Creeth), 210
Molecular Weight Solutes : Use of High, in the Study of Isolated Intracellular Structures (Dr. John H. McClendon and Prof. L. R. Blinks), 577
Molecules (Diatomic) : Forbidden Transitions in (Dr. G. Herzberg), 832
Molecules (Polyatomic) : Electronic Orbitals, Shapes and Spectra of (Dr. A. D. Walsh), 974
Mollusc Control and Fish-Farming in Central Africa (Dr. A. F. De Bont and M. J. De Bont Hers), 323
Molybdenum in relation to Cropping and Livestock Problems under Irish Conditions (Dr. T. Walsh, M. Neenan and Dr. L. B. O'Moore), 149
Molybdenum Carbide : A New (K. Kuo and G. Hägg), 245
Molybdenum Deficiency in Florida Citrus (Dr. Ivan Stewart and C. D. Leonard), 714
Momentum : Angular, in Dirac's New Electrodynamics (R. W. Iskraut), 1125
Momentum Tensor : The Energy, in Dirac's New Electromagnetic Theory (Prof. Banesh Hoffmann), 1126
Mono-Sulphite Processes : Pulping of Illuk Grass (*Imperata arundinacea*) by Soda and (Chattar Singh and Dr. S. R. D. Guha), 27
Monobasic Organic Acids : Acid Salts of—a New Series of Primary Standards for Alkalimetry (Dr. Neville Smith), 538

Monolayers (Bovine Serum Albumin) : Ionization of (M. Z. Dogan and Dr. J. Glazer), 417
Monolayers (Fatty Acid and Protein) : Tanning of, by Metal Ions (Cr, Al, Fe and Co), (Dr. J. H. Schulman and M. Z. Dogan), 31
Montmorillonite : A Test for (R. Greene-Kelly), 1130
Moonlight and the Pregnancy of Malayan Forest Rats (J. L. Harrison), 73
Moorland : Afforestation of (British Association for the Advancement of Science, Section K* (Forestry), Discussion on), 734
Morphogenesis : An Essay on, *review* by Prof. C. W. Wardlaw, 943
  The Chemical Basis of (Dr. A. M. Turing), 955
Morphogenesis, an Essay on Development (John Tyler Bonner), *review* by Prof. C. W. Wardlaw, 943
Morphogenesis in Plants (Prof. C. W. Wardlaw), *review* by Prof. Edmund W. Sinnott, 990
Mosquitoes : Contrasting Methods of Transmission of Animal Viruses by (Prof. Frank Fenner and Dr. M. F. Day), 204
  Filarial Infections in (N. G. S. Raghavan, B. G. Misra and Radhagovinda Roy), 253
Mosquitoes (Adult) : Experiments on the Use of DDT, BHC and Dieldrin against, at Taveta, Kenya (G. Davidson), 702
Motor End-Plate Differences as a Determining Factor on the Mode of Action of Neuro Muscular Blocking Substances (Dr. Eleanor J. Zaimis), 617 ; (H. C. Churchill-Davidson and A. T. Richardson), 617
Mountbatten Medal of the British Institution of Radio Engineers awarded to C. J. White, 308
Mouse (House) : A New Linkage in the—Vestigial and Rex (Donald Michie), 585
Mouse (Ovariectomized) : Response of the Vaginal Epithelium of the, to the Systemic and Local Administration of Œstrone (J. D. Biggers), 895
Mouse Sarcoma : Transplantation of, with Small Numbers of Single Cells (H. B. Hewitt), 622
Mouse Tumours : Relative Biological Effectiveness of Betatron and Conventional X-Radiation on the Regression of (Dr. T. P. King, Dr. H. E. Jones and Prof. L. B. Jaques), 752
Movements of the Alimentary Canal : Nervous Control of the (Prof. R. C. Garry), 398
Moving a Factory (Roy Lewis), 268
Mucoprotein (Urine) : Carbohydrate Residue of a, Inhibiting Influenza Virus Hæmagglutination (Dr. Alfred Gottschalk), 662 ; (Dr. L. Odin), 663
Multiplication of Influenza Virus under Conditions of Interference (Dr. S. Fazekas de St. Groth, Dr. A. Isaacs and Miss Margaret Edney), 573
Murchison Fund for 1953 of the Geological Society of London awarded to C. D. Ovey, 1098
Murchison Medal for 1953 of the Geological Society of London awarded to Dr. F. Dixey, 1098
Muscle (Dried) : Extractability of the Lotmar-Picken Material from (Dr. H. E. Huxley and Dr. J. C. Kendrew), 882
Muscle (Red and White) : Biochemical Differences between (R. A. Lawrie), 122
Muscle (Striated) : Supra-vital Staining of, with Tetrazolium Compounds (G. Calcutt), 42
Muscle Fibre Models : Effect of the 'Marsh Factor' on the Shortening of, in the Presence of Adenosine Triphosphate (J. R. Bendall), 1058
Muscles : Comparative Physiology of (British Association for the Advancement of Science, Sections D (Zoology) and I (Physiology), Discussion on), 996
Muscular Atrophy : Changes in the Flow Birefringence of Myosin as a result of (Georges Schapira, Jean-Claude Dreyfus and Maurice Joly), 494
Museum Lighting : Extreme Ultra-Violet Radiation from Tubular Fluorescent Lamps and its Effect on (J. Genard), 306
Museum Teaching : Changing Fashions in (Peter Flood), 354
Museums : Fluorescent Lighting in, 306, 441
  The Inevitability of (S. D. Cleveland), 354
Museums and Education (Unesco Seminar on), 307
Mutagenic Effects on Cereal Seeds : X-Ray and Neutron, 1112
Mutagenic Reagents : Site of Action of—Nitrogen Mustards (Miss M. J. Ord and Prof. J. F. Danielli), 921 ; X-Rays (Dr. E. B. Harriss, Dr. L. F. Lamerton, Miss M. J. Ord and Prof. J. F. Danielli), 922
Mycobacterium tuberculosis avium : Lactic Oxidases of (Yuichi Yamamura, Masamiti Kusunose and Emi Kusunose), 207
Myosin : Changes in the Flow Birefringence of, as a result of Muscular Atrophy (Georges Schapira, Jean-Claude Dreyfus and Maurice Joly), 494
Mystacocaridea (Crustacea) : A New Species of the (Dr. Erik Dahl), 75
Mytilus edulis and Two Gastropod Veligers : Efficiency of Growth in (C. Barker Jørgensen), 714
Myxomatosis in Australia—a Step towards the Biological Control of the Rabbit (F. N. Ratcliffe, K. Myers, B. V. Fennessy and J. H. Calaby), 7
Myzus circumflexus (Buck.) : Occurrence of Gamma-Amino Butyric Acid in Extracts of *Pisum sativum* (L.) and in the Honeydew of (J. L. Auclair and J. B. Maltais), 1114

NAMES : Common, of British Insect Pests, 346
Narcissus : Trimorphism and Self-incompatibility in (A. J. Bateman), 496
National Fuel Problems in Great Britain, 827
National Intelligence : Level of (Dr. John D. Nisbet), 852
National Parks and Local Government, 333
National Security : International Scientific Relations and, 1033
Nationalized Industries : Organization of, 144
Natural History, Annals and Magazine of : To combine with the *Journal of Botany*, 405
Natural History at Edinburgh, 403
Natural History of Bacteria, *review* by Dr. S. T. Cowan, 133
Natural Science, Industrial Research, Virology and Agriculture : Fellowships in (British Memorial Fund in Victoria, Australia), 189
Nature : Mind and its Place in (Manson Lectures for 1952 of the Royal Institute of Philosophy), 608
Naval Architecture and Marine Engineering : Scholarships in (Institution of Naval Architecture), 1049
Nebula NGC 4216 (Spiral) : A Diffraction Corona near the Centre of the (Prof. Bertil Lindblad and Aina Elvius,) *erratum*, 61
Nerve Cells in *Lingula* : Giant (P. Kirtisinghe), 206
Nerve Impulses : Energy into (British Association for the Advancement of Science, Section I (Physiology), Discussion on), 823
Nerve Impulses originating from the Compound Eye of the Locust (E. T. Burtt and W. T. Catton), 285
Nervous Control of the Movements of the Alimentary Canal (Prof. R. C. Garry), 398
Neuro-Muscular Blocking Substances : Motor End-Plate Differences as a Determining Factor in the Mode of Action of (Dr. Eleanor J. Zaimis), 617 ; (H. C. Churchill-Davidson and A. T. Richardson), 617
Neurones (Spinal Ganglion) : Senility Changes in the, of the Toad, *Bufo regularis* (Dr. Tohamy A. Moussa), 206
Neurospora following a Volcanic Eruption (Prof. Alan Burges and Barbara Chalmers), 459
Neutron Mutagenic Effects on Cereal Seeds : X-Ray and, 1112
Neutron Resonance Parameters : Determination of, from Measurements of the Absorption Integral—Application to the Main Resonance of Uranium-238 (G. v. Dardel and R. Persson), 1117
Neutrons from the Reaction ^{7}Li(*d*,*n*)^{8}Be : Angular Distribution of the (Prof. B. Trumpy, T. Grotdal and A. Graue), 1118
New Caledonian Beeches : Identification of Tertiary Pollen Grains with those of New Guinea and (Dr. Isabel C. Cookson), 127
New Guinea and New Caledonian Beeches : Identification of Tertiary Pollen Grains with those of (Dr. Isabel C. Cookson), 127
New Zealand : Forest Taxation in (M. B. Grainger), 482
New Zealand Soils : Abnormal Thermal Behaviour of α-Quartz from some (M. Fieldes), 366
Newspaper Libraries (J. Lewis), 563
Newton's Third Law : Electromagnetic Momentum and (Prof. E. G. Cullwick), 425
Newtonian Systems : Modified (Dr. R. Capildeo), 936
Nickel : Magnetostrictive Effect and the Δ-*E* Effect in (Henrik Nordvedt), 884
Nicotinic Acid : Estimation of the 'Bound Form' of (Dr. K. K. Reddi), 745
Nilomètre de l'Île de Rodah : Le Mikyas ou (Kamel Osman Ghaleb Pasha), *review* by Dr. H. E. Hurst, 132
N-Nitration and *O*-Nitration by the Nitronium Ion (Eileen L. Blackall and Prof. E. D. Hughes), 972
Nitric Oxide : Reaction between Diethyl Peroxide and (H. N. Mortlock and Dr. D. W. G. Style), 706
Nitrifying Bacteria : Minimum Phosphate and Magnesium Requirements of (Dr. Jane Meiklejohn), 1131
Nitrite : Effect of, on the Nuclear Structure in the Silkworm (Prof. Kazuo Yamafuji), 126
Nitrocellulose (Dissolved) : Pyrolysis of (R. D. Smith), 844
Nitrogen (Plant) : Quantitative Paper Chromatography of (J. F. Thompson and F. C. Steward), 828
Nitrogen Compounds with Four Condensed Rings : Six-Membered Heterocyclic (C. F. H. Allen, in collaboration with D. M. Burness, Jean V. Crawford, F. W. Spangler, Eleanor R. Webster and C. V. Wilson), *review*, 384
Nitrogen Mustards : Site of Action of Mutagenic Reagents—(Miss M. J. Ord and Prof. J. F. Danielli), 921
Nitronium Ion : *N*-Nitration and *O*-Nitration by the (Eileen L. Blackall and Prof. E. D. Hughes), 972
Nitrophenanthridinium Salts : Reduction of—Influence of Molecular Size on Trypanocidal Activity (Dr. L. P. Walls and E. Beveridge), 666
Nitrosyl Chloride : The Hydrogen–Oxygen Reaction Sensitized by (J. Chanmugam and Dr. P. G. Ashmore), 1067
Nobel Prize for Chemistry for 1952 awarded jointly to Dr. A. J. P. Martin and Dr. R. L. M. Synge, 826
Nobel Prize for Physics for 1952 awarded jointly to Prof. E. M. Purcell and Prof. Felix Bloch, 911
Nobel Prize for Physiology and Medicine for 1952 awarded to Prof. S. A. Waksman, 782
Noise Equivalent Input of Radiation : 'Detectivity', the Reciprocal of (R. Clark Jones), 937
Nomenclature : Anatomical, 186
  Zoological (Francis Hemming), 503, 938
Non-aqueous Solutions : Conductance in (R. C. Schonebaum), 422
Noradrenaline and Accessory Chromaffin Tissue (D. M. Shepherd and Dr. G. B. West), 42
North America (Western) : Amphibians of (Robert C. Stebbins), *review* by Dr. H. W. Parker, 768
North American Buffalo : The (Frank Gilbert Roe), *review* by Dr. Maurice Burton, 945
North Pole (Geographical) : Arctic Aerobiology—Fungi and Bacteria, etc., caught in the Air during Flights over the (Prof. Nicholas Polunin and Dr. C. D. Kelly), 314
Nostoc muscorum : Necessity of Boron for (Clyde Eyster), 755
Nuclear Physics : High-Energy (National Science Foundation and the University of Rochester Conference on), 914
  Medium-Energy (University of Pittsburgh Conference on), 349
Nuclear Science : Annual Review of, Vol. 1, *review* by Dr. W. D. Allen, 857
  Philosophic Problems of (Werner Heisenberg), translated by F. C. Hayes, *review* by F. I. G. Rawlins, 591
  Progress in, *review* by Dr. W. D. Allen, 857
Nuclear and Cytoplasmic Actions of Drugs : Separate (Prof. J. F. Danielli), 1042
Nuclear and Fundamental Particle Physics (Dr. S. C. Curran), 512
Nuclear Reactors : Course of lectures on (City and Guilds College, London), 308
Nuclear Shells from Atomic Mass Measurements : Evidence for (Prof. Henry E. Duckworth), 158
Nuclear Structure in the Silkworm : Effect of Nitrite on the (Prof. Kazuo Yamafuji), 126
Nucleation : Dielectric Observations of (Dr. Vera Daniel and Mrs. Clara Turner), 1122
Nuclei : Forbidden Transitions in (L. G. Elliott), 832
Nuclei (Atomic) : Statistical Theory of (Prof. P. Gombás), 362
Nuclei (Light) : Excited States of, 512
Nuclei of Heterozygous Diploid *Aspergillus* : Non-random Distribution of Multiple Mitotic Crossing-over among (Dr. G. Pontecorvo), 204
Nucleic Acid Metabolism during Insect Metamorphosis (Dr. Ivar Agrell), 543
Nucleic Acids (Bacteriophage) : A New Pyrimidine Base from (Dr. G. R. Wyatt and Dr. S. S. Cohen), 1072

Nucleic Acids of Rickettsiae (Dr. G. R. Wyatt and Dr. S. S. Cohen), 846
Nucleolar Material in the Female Germ-Cells of *Lumbricus terrestris* L.: Extrusion of (D. S. Srivastava), 757
Nucleoprotein (Tobacco Mosaic Virus): Infra-Red Dichroism of (Dr. R. D. B. Fraser), 491
5-Nucleotidase: Serum (Dr. T. F. Dixon and M. Purdom), 500
Nupserha bicolor Thoms., subsp. *postbrunnea* Breun., a New Pest on Jute (*Corchorus olitorius* Linn.), (N. Dutt), 287
Nutrition: Second International Congress on, 652
  Mineral, of Plants (edited by Emil Truog), *review* by Dr. G. Bond, 176
Nutrition (Animal): Antibiotics in (British Association for the Advancement of Science, Sections I (Physiology) and M (Agriculture), (Discussion on), 868
Nutrition (Mineral): Influence of, on the Resin Content of the Hop Cone (F. C. Thompson and Dr. A. H. Burgess), 890
Nutrition of Ruminants: Cobalt in the—Response of Cobalt-deficient Sheep to Massive Doses of Vitamin B_{12} (Hedley R. Marston and H. John Lee), 791; Control of Cobalt-deficiency in Sheep by Injection of Vitamin B_{12} (Hedley R. Marston and Richard M. Smith), 792; Influence of Cobalt on the Production of Factors possessing Vitamin B_{12}-like Activity in the Faeces of Sheep (Mary C. Dawbarn, Denise C. Hine and Patricia Hughes), 793
Nutrition and Household Science: University Degrees in, 226
Nutritional Research: Present Problems in (International Union of Nutritional Sciences Symposium on), 442
Nutritive for *Vibrio cholerae*: Glycerol as a (Dr. Deborah Kaplan and Dr. Walter Koch), 165
Nyasaland (Southern): A New Province of Igneous Ring-Complexes in (K. V. Stringer), 630

OAK Ridge 86-inch Cyclotron (Dr. Robert S. Livingston), 221
Oats: Lysenko's Latest Discovery—The Conversion of Wheat into Rye, Barley and (Prof. P. Maheshwari), 66
Objectivity of Colour Preferences (Dr. G. W. Granger), 778
Occult: The Psychology of the (D. H. Rawcliffe), *review* by Dr. E. J. Dingwall, 176
Occultation of a Radio Star by the Solar Corona (K. E. Machin and F. G. Smith), 319
Oersted Medal of the American Association of Physics Teachers presented to Prof. A. A. Knowlton, 612
Œstradiol Benzoate and Orchidectomy: Effect of, on the Toxicity of Trypan Blue (Prof. T. Nicol and A. A. Zikry), 239
Œstrogenized Immature Pullet: Vitamin A Ester and Vitamin A Alcohol in the Serum of the (V. E. Gardiner, W. E. Phillips, W. A. Maw and Prof. R. H. Common), 80
Œstrogens (Natural): Chromatographic Isolation and Estimation of the, from Tissue (F. L. Mitchell), 621
Œstrone: A New Route to (B. K. Bhattacharyya and P. Sengupta), 710
  Response of the Vaginal Epithelium of the Ovariectomized Mouse to the Systemic and Local Administration of (J. D. Biggers), 895
Œstrus: Inhibition of, by Cultivated Gromwell (Dr. B. P. Wiesner and Prof. John Yudkin), 274
Oil in Pakistan (M. J. Condon), 783
Oil Pollution of the Sea, 738
Oils (Fatty): Hydrogenation of (Prof. H. I. Waterman, with the collaboration of C. Boelhouwer and L. J. Revallier), *review* by Dr. H. Jasperson, 175
Oils and Fats: The Chayen Process for Extraction of (Dr. J. M. Coulson), 881
  Hydrogenation of, *review* by Dr. H. Jasperson, 175
Old: On Growing, *review* by Prof. P. B. Medawar, 260
Ophiuroid Genus *Ctenamphiura* Verril: Rediscovery of the (Dr. H. Barraclough Fell), 327
Optical Fourier Synthesis: Improvements in (A. W. Hanson), 580
Optik (Prof. Arnold Sommerfeld), *review* by Prof. R. E. Peierls, 684
Orbitals, Shapes and Spectra of Polyatomic Molecules: Electronic (Dr. A. D. Walsh), 974
Orchidectomy: Effect of Œstradiol Benzoate and, on the Toxicity of Trypan Blue (Prof. T. Nicol and A. A. Zikry), 239
Orcinol Test Specific for Ketose Sugars: An Extended (J. Howarth Williams), 894
Organic Analysis (Qualitative): A Text-Book of Practical Organic Chemistry, including (Dr. Arthur I. Vogel), second edition, *review* by Prof. J. W. Cook, 727
Organic Chemists' Vade-Mecum, *review*, 508
Organic Compounds: Chemistry of (Prof. Carl R. Noller), *review* by G. Fowles, 431
  Fluorescence of, *review* by Dr. E. J. Bowen, 296
  Identification of, from Infra-Red Spectra (Dr. A. E. Martin), 20
Organic Intermediates: Preparation of (Prof. David Allen Shirley), *review* by J. Idris Jones, 817
Organic Matter: Decomposition of, by Recoil Atoms from an Adjacent Phase (D. F. Sangster and J. Wright), 368
Organic Matter Content: Modification of a Soil Percolation Apparatus for Soils of a High (T. M. B. Payne and P. H. H. Gray), 325
Organic Solvents: Flattening of Meniscus between Water and (Dr. A. F. H. Ward and L. H. Brooks), 118
Organization: Patterns of (Acton Society Trust, Nationalized Industry Series No. 9), 144
Organischer Verbindungen: Fluoreszenz (Prof. Theodor Förster), *review* by Dr. E. J. Bowen, 296
Organization of Behavior, a Neuropsychological Theory (Prof. D. O. Hebb), *review* by Dr. John Cohen, 297
Organization of Nationalized Industries, 144
Organophosphorus Compounds (Prof. Gennady M. Kosolapoff), *review* by J. Idris Jones, 637
Origin of Species: Genetics and the (Prof. Theodosius Dobzhansky), third edition, *review* by Prof. K. Mather, 383
Origin, Variation, Immunity and Breeding of Cultivated Plants (Selected writings of N. I. Vavilov), translated from the Russian by Dr. K. Starr Chester, *review* by Prof. S. C. Harland, 48
Ornithological Congress at Bamburgh, 227
Ornithologist's Vade-Mecum: British Amateur, *review* by R. M. Lockley, 944
Ornithology of the Channel Isles, *review*, 769
Ornithology in the U.S.S.R. (Dr. Hans Johansen), 28
Oscillation of Alkali Halide Crystals: Polarization Field and the Acoustic Modes of (Sir K. S. Krishnan and S. K. Roy), 159
Oscilloscopes and their Uses: Encyclopedia on Cathode-Ray (John F. Rider and Seymour D. Uslan), *review* by G. E. Ashwell, 684
Otology: Alexander Pigott Wernher Memorial Travelling Fellowships in (Medical Research Council Awards), 189
Ovalbumin to Plakalbumin: Stepwise Degradation of the Peptides liberated in the Transformation of (Martin Ottesen and Albert Wollenberger), 801
Ovariectomized Mouse: Response of the Vaginal Epithelium of the, to the Systemic and Local Administration of Œstrone (J. D. Biggers), 895
Ovary (Rat): Growth of, in Tissue Culture (Jean J. Scott), 208
Overseas: Food Science at Home and (Institute of Rural Life at Home and Overseas, the Association of Agriculture and the University of London Institute of Education Meeting on), 829
Overseas Dominions: Aspects of Settlement in the (Prof. R. O. Buchanan), 395
Overseas Information Services, 633
Overseas Information and Broadcasting Services (Foreign Office Committee on), 738
Ovine Ketosis: Acetate Metabolism in (P. Storie Pugh and R. Scarisbrick), 978
Oxford Synchrotron, 913
Oxidation of Pyruvate: Role of Sulphydryl Groups in the (Dr. E. C. Slater), 970
Oxidation of Thiophosphate Insecticides in the Rat (D. K. Myers, Prof. B. Mendel, H. R. Gersmann and Prof. J. A. A. Ketelaar), 805
β-Oxidation of ω-Phenoxyalkylcarboxylic Acids in the Flax Plant (C. H. Fawcett, J. M. A. Ingram and Prof. R. L. Wain), 887
Oxidative Degradation of Testosterone by Adaptive Enzymes (Dr. Paul Talalay, Marie Mollomo Dobson and Donald F. Tapley), 620
Oxidative Phosphorylation in Heart-Muscle Sarcosomes: Stabilization of (Dr. E. C. Slater and Dr. K. W. Cleland), 118
Oxide Cathode Emission: Poisoning of, by Oxygen (Dr. A. A. Shepherd), 839
Oxide Films: Surface, in Intermetallic Contacts (M. Cocks), 203
l'Oxydation: Le mécanisme de, Rapports et discussions (Institut International de Chimie Solvay, Huitième Conseil de Chimie tenu à l'Université de Bruxelles, Septembre 1950), *review* by Prof. J. R. Partington, 944
Oxygen: Poisoning of Oxide Cathode Emission by (Dr. A. A. Shepherd), 839
Oxygen Clathrate Compound: Preparation and Magnetic Susceptibility of an (D. F. Evans and Dr. R. E. Richards), 246
Ozone at High Dilutions: Electrometric Determination of (Dr. J. N. Pring and G. M. Westrip), 530

PACIFIC: Seismic Refraction Experiments in the (Dr. T. F. Gaskell and J. C. Swallow), 1010
Pacific Ocean (Eastern North): Heat Flow through the Floor of the (Roger Revelle and Arthur E. Maxwell), 199; (Dr. E. C. Bullard), 200
Packed Red-Cell Volume in the Tropics (Dr. G. R. Wadsworth), 851
Pakistan: Oil in (M. J. Condon), 783
Palaearctic and Indian Mammals, 1758 to 1946: Checklist of (J. R. Ellerman and T. C. S. Morrison-Scott), review by Dr. L. Harrison Matthews, 298
Paléolithique et le mésolithique du Désert de Judée (René Neuville), *review* by M. C. Burkitt, 386
Palestine (Eastern): The Stone Age in, *review* by M. C. Burkitt, 386
Palladium–Rhodium Alloys at 20° to 300° K.: Magnetic Susceptibilities of (Dr. F. E. Hoare, J. S. Kouvelites and J. C. Matthews), 537
Pancreas (Rat): Rapid Restitution of the, following Acinar Cell Necrosis subsequent to Ethionine (Dr. Patrick J. Fitzgerald and Dr. Mario Alvizouri), 929
Pancreatic Digestion: A Difference in *in vitro*, between Animal and Plant Protein Feeds (Dr. A. Bondi and Mrs. Yehudith Birk), 673
Paper Industries: United States Pulp and, 965
Paper Pulp Research at the Dehra Dun Research Institute, 27
Papers (Writing and Printing): Pulps for, from the Castor Oil Plant *Ricinus communis* (Dr. R. V. Bhat and Narendra S. Jaspal), 28
Papierchromatographie (Dr. Friedrich Cramer), *review* by Dr. R. Consden, 50
Papyrography: Ultra-Violet—An Automatic Analytical Apparatus using Filter Paper without a Colour Reagent (Dr. Yohei Hashimoto and Itsuhiko Mori), 1024
Paraffins (Normal): Thermal Decomposition of (Clifford G. Silcocks and Prof. Morris W. Travers), 1028; (Sir Cyril Hinshelwood and C. J. Dandy), 1029
Parasites: Bird, *review* by Dr. E. Hindle, 382
Parasites and Parasitism, *review*, 218
Parasitic Animals (Dr. Geoffrey Lapage), *review*, 218
Parasitism: Parasites and, *review*, 218
Parasitism and Symbiosis (Maurice Caullery), translated by Dr. Averil M. Lysaght, *review* by Dr. G. Lapage, 91
Paris to London Television Relay, 101
Parks: National, and Local Government, 333
Parthenogenesis: Some Problems of (Prof. A. D. Peacock), 395
Particle Physics: Nuclear and Fundamental (Dr. S. C. Curran), 512
Particle-Sizing by Successive Countings: Automatic (P. G. W. Hawksley), 984
Particles: Fundamental (S. Weintroub), 447
Particles (Fine): Measurement of Thicknesses of (W. H. M. Robins), 583
Particles (Microscopic Spherical): A Method of Measuring and Grading, (Dr. V. Timbrell), 318
Particles (Relativistic): Ionization Loss by (Autumn Provincial Meeting of the Physical Society on), 653
Particles and Wave Fields: Quantum Mechanics of (Prof. Arthur March), *review* by Prof. G. Temple, 727
Pasture and Fodder Development in Mediterranean Countries (Prof. N. M. Comber), 56
Patents: Terrell and Shelley on the Law of, ninth edition, by K. E. Shelley, *review* by R. G. Lloyd, 49
Patient with Acute Porphyria: Isolation of Porphobilinogen from the Urine of a (R. G. Westall), 614

TITLE INDEX

Patterns of Organization (Acton Society Trust, Nationalized Industry Series No. 9), 144
Pea Plant . Triosephosphate Dehydrogenase and Glucose-6-Phosphate Dehydrogenase in the (Dr. Martin Gibbs), 164
Peace and War   Protection of Cotton in, *review*, 594
Peak District : Preservation of the, 954
Pear–Apple Hybrids (M. B. Crane and E. Marks), 1017
Pectic Acid : Enzymic Degradation of, and the Complex Nature of Polygalacturonase (Audrey Ayres, J. Dingle, A. Phipps, W. W. Reid and G. L. Solomons), 834
Pectinase Technique for Isolating Plant Cells (J. Chayen), 1070
Peintures : Notions fondamentales sur les vernis et (Louis Kientz), deuxième édition, *review* by Dr. A. E. A. Werner, 52
Pelagia in Manx Waters (Prof. F. J. Cole), 587
Pellicularia koleroga Cooke in Pure Culture . Growth-Factor Requirements of (K. T. Mathew), 889
Penetration of the Egg in Mammals   Passage of the Sperm and the (C. R. Austin and A. W. H. Braden), 919
Pentanisia variabilis (E. Mey.) Harv. (Rubiaceae)   Production of Antibiotic Substances by the Roots of a Grass (*Trachypogon plumosus* (H. B. K.) Nees) and of (Gordon Stiven), 712
Pentose Phosphates   Formation and Breakdown of, by Liver Fractions (Dr. Gertrude E. Glock), 162
Pepsinogen in Human Seminal Fluid (Dr. Frank Lundquist and Dr. Hans Henrik Seedorff), 1115
Peptide Link : Configuration of the, and of Asparagine in Glycyl-L-Asparagine (Dr. Lewis Katz, R. A. Pasternak and Prof. Robert B. Corey), 1066
Peptide-Bond Synthesis   Reported Gamma Glutamyl Activation of (Richard W. Hendler and Prof. David M. Greenberg), 123
Peptides   Salting-out Chromatography of Amino-acids and, in Filter Paper and other Media (L. Hagdahl and Prof. A. Tiselius), 799
Peptides liberated in the Transformation of Ovalbumin to Plakalbumin : Stepwise Degradation of the (Martin Ottesen and Albert Wollenberger), 801
Perchloric Acid : Action of X-Rays on Aqueous Solutions of (B. Milling, Dr. G. Stein and Dr. J. Weiss), 710
Perfused Cat's Brain : Survival of the, in the Absence of Glucose (A. Geiger, J. Magnes and R. S. Geiger), 754
Periodicals : Scientific and Technical, published in South-East Asia (Unesco East Asia Science Co-operation Office), 59
Periodontal Tissues of Rats' Incisor Teeth   Macrophages in the (Prof. J. T. Irving), 573
Perkin Medal for 1953 of the American Section of the Society of Chemical Industry awarded to Dr. Charles Allen Thomas, 954
Permafrost Drilling and Soil-Temperature Measurements at Resolute, Cornwallis Island, Canada (Andrew Thomson and P. C. Bremner), 705
Permeability of Isolated Rat Heart Sarcosomes (Dr. K. W. Cleland), 497
Permeability of Yolk of the Hen's Egg to Bromine-82 (D. M. Maurice and A. Fidanza), 546
Permeability of Yeast   Cellular, to Metallic Ions (E. Quagliozzi and A. Rescigno), 35 , *erratum*, 103
Peroxidation of Unsaturated Ketones (Dr. Ernest Wenkert and Mordecai Rubin), 708
Personality   The Assessment of (Prof. P. E. Vernon), 398
Personnel in Industrial Research . Selection, Training and Use of (Proceedings of the Second Annual Conference on Industrial Research, June 1951, sponsored by the Department of Industrial Engineering, Columbia University, edited by David B. Hertz and Albert H. Rubenstein), 941
'Perspex' for Darkroom Lights   Coloured (L. A. T. Ballard), 840
Pertussis Vaccine   The Standardization of (Dr. P. W. Muggleton), 236
Pest on Jute (*Corchorus olitorius* Linn.) : *Nupserha bicolor* Thoms., subsp. *postbrunnea* Breun., a New (N. Dutt), 287
Pests (British Insect) : Common Names for, 346
Petrography . Sedimentary (Henry B. Milner), third edition, *review*, 511
Petroleum Consumption and Refinery Production in Great Britain during 1951 (Petroleum Information Bureau), 268
Petrological Identification of Stone Axes, 828
pH and Biological Activity : Ionization, (Dr. H. C. S. Wood), 994
pH Meters : Centrifuges and (Institute of Biology Survey of), 229
Phanomenologie und phanomenologischen Philosophie : Ideen zu einer reinen (Edmund Husserl), Buch 1, neue Auflage herausgegeben von Walter Biemel, Buch 2, herausgegeben von Marly Biemel, Buch 3, herausgegeben von Marly Biemel, *review* by F. I. G. Rawlins, 470
Pharmaceutical Codex 1949 : The British, Supplement 1952 (Pharmaceutical Society of Great Britain), *review*, 818
Pharmaceutical Conference, 1952 : British (S. B. Challen), 787
Pharmaceutical Research Fellowships . Wellcome, awarded to J. Thomas and G. L. Willey, 346
Pharmacist : An Education for a (H. B. Mackie), 787
Pharmacological and Toxicological Actions of Dart Poison used in Malaya (Robert Chun Yu Lin), 416
Phase Equilibria   Principles of (F. E. W. Wetmore and D. J. LeRoy), *review* by Prof. J. R. Partington, 859
Phase Rule : The, *review* by Prof. J. R. Partington, 859
Phase Rule and Heterogeneous Equilibrium (Prof. John E. Ricci), *review* by Prof. J. R. Partington, 859
Phenolic Substances   Paper Chromatography of (G. M. Barton, R. S. Evans and J. A. F. Gardner), 249
Phenomenology   Transcendental, *review* by F. I. G. Rawlins, 470
ω-Phenoxyalkylcarboxylic Acids in the Flax Plant : β-Oxidation of (C. H. Fawcett, J. M. A. Ingram and Prof. R. L. Wain), 887
Phenyl Radicals in Solution and in the Gaseous Phase : Reactions of (M. T. Jaquiss and Dr. M. Szwarc), 312
'Philadelphia Experiment' on Lightning : Franklin's, 1099
Philosophic Problems of Nuclear Science (Werner Heisenberg), translated by F. C. Hayes, *review* by F. I. G. Rawlins, 591
Philosophical and Biographical Essays, *review* by Prof. A. D. Ritchie, 992
Philosophie (phanomenologischen)   Ideen zu einer reinen Phanomenologie und (Edmund Husserl), Buch 1, neue Auflage herausgegeben von Walter Biemel, Buch 2, herausgegeben von Marty Biemel, Buch 3, herausgegeben von Marty Biemel, *review* by F. I. G. Rawlins, 470
Philosophy : Ethics and the History of (Prof. C. D. Broad), *review* by Prof. A. D. Ritchie, 992
  Moral, and Social Anthropology, *review* by Lord Raglan, 174
Philosophy for Modern Man, *review* by R. Brightman, 1085
Philosophy of Management, *review* by E. F. L. Brech, 430
Phosphatase (Alkaline) . Coupling Azo Dye Methods for Histochemical Demonstration of (Dr. E. Grogg and Dr. A. G. Everson Pearse), 578
Phosphatase Activity : Zinc, Ionic Equilibrium and (V. Sadasivan), 421
Phosphate and Magnesium Requirements . Minimum, for Nitrifying Bacteria (Dr. Jane Meiklejohn), 1131
Phosphates (Pentose) . Formation and Breakdown of, by Liver Fractions (Dr. Gertrude E. Glock), 162
Phosphoric Esters   Paper Chromatography of (S. Burrows, F. S. M. Grylls and J. S. Harrison), 800
Phosphorus   Organic Chemistry of, *review* by J. Idris Jones, 637
Phosphorus (White) . Structure of—Single Crystal X-Ray Examination (D. E. C. Corbridge and E. J. Lowe), 679
Phosphorus as a Factor Preventing DDT-Dehydrochlorination (H. Maas), 328
Phosphorus Making, 1851–1951 . The Story of 100 Years of (Richard E. Threlfall), *review*, 595
Phosphorylation and Xylose by Extracts of *Pseudomonas hydrophila* (Dr. Rolf M. Hochster and Dr. R. Wade Watson), 357
Phosphothreonine   Isolation of, from Bovine Casein (C.-H. de Verdier), 804
Photodisintegration, 514
Photo-Elastic Determination of Boundary Stresses (William Shelson), 82
Photoelectric Absorptiometer : New, 694, 784
Photographic Image produced by Beta-Rays . Intensification of the Latent (Prof. K. Zuber), 669
Photography : The Applications of, to Research in the University (Scientific and Technical Group of the Royal Photographic Society Symposium on), 348, 879
  International Conference on the Science and Applications of (Royal Photographic Society), 694
Photoperiodic Behaviour of *Hibiscus sabdariffa*, *L.N.P.*5 (Sumitra Talukdar), 458
Photosynthesis and Concentration of Carbon Dioxide in *Chlorella*   Rate of (Dr. C. P. Whittingham), 1017
Physical Concepts, New and Old, *review* by F. I. G. Rawlins, 726
Physical Properties and Analysis of Heavy Water (Isidor Kirshenbaum), edited by Harold C. Urey and George M. Murphy, *review* by Prof. H. J. Emeléus, 635
Physicist Looks Forward, *review* by Sir John Russell, 636
Physicists   Scientific Education of (Institute of Physics), 196
Physicists and Electrical Engineers : Abstracting for, *review* by S. Weintroub, 338
Physics. Low Temperature (F. E. Simon, N. Kurti, J. F. Allen, K. Mendelssohn), *review* by S. Weintroub, 1088
  New Research Techniques in (Academia Brasileira do Ciencias and Unesco Centro de Cooperación Cientifica para América Latina Symposium on), 19, 700
  Nuclear and Fundamental Particle (Dr. S. C. Curran), 512
  Recent Progress in, *review* by S. Weintroub, 90
  Reports on Progress in, Vol. 14 (1951), *review* by S. Weintroub, 90
Physics (Applied), British Journal of (edited by Dr. H. R. Lang), Vol. 2, and Supplement No. 1, 1951, *review*, 473
Physics (Experimental) . Contributors to, from Britain (Prof. A. M. Tyndall), 393
Physics at King's College, London : Engineering, Biophysics and—New Building (Dr. M. H. F. Wilkins), 261
Physics in the United States   Annual Meetings of the American Physical Society and of the American Association of Physics Teachers, 612
  Current Trends of (Dr. J. C. Overbeck), 187
Physics Abstracts, Vol. 54, 1951, *review* by S. Weintroub, 338
Physik (theoretische)   Vorlesungen uber (Prof. Arnold Sommerfeld), Band 4, Optik, *review* by Prof. R. E. Peierls, 684
Physiologie . Vergleichende (Prof. W. von Buddenbrock), Band 4, Hormone, *review*, 858
Physiology in the United States (American Physiological Society Survey of), 268
Physiology in the University of London, 736
Physiology of Mitosis, *review* by Prof. W. S. Bullough, 51
Physiology of Muscles : Comparative (British Association for the Advancement of Science, Sections D (Zoology) and I (Physiology), Discussion on), 996
Physique moderne théorique : Éléments de (Georges Guinier), Vol. 3, Statistiques quantiques, *review* by Prof. G. S. Rushbrooke, 682
Phytopathology : Agricultural, *review* by Dr. S. G. Jones, 860
Phytophthora palmivora : Airborne Dispersal of, causing Black-Pod Disease of *Theobroma cacao* (C. A. Thorold), 718
Phytotoxic Action of 2 4 Dichlorophenoxyacetic Acid : Effects of Preliminary Treatment on the Subsequent Variation in the Resistance of *Lemna minor* to the (R. C. Robertson-Cuninghame and Prof. G. E. Blackman), 459
Phytotoxicity of Histamine, Arsenic Acid and Dichlorophenoxyacetic Acid, and Methods of Testing (C. G. Greenham), 535
Pieris rapae L. : Sex in, and Pteridin Content of their Wings (Dr. Katashi Makino, Kiyoo Satoh, Masahiko Koike and Naomichi Ueno), 933
Pig Strains of *Ascaris*   Anatomical Distinction between Human and (Dr. J. F. A. Sprent), 627
Pigment in Sheep Skin Autografts : Spread of (Dr. Margaret H. Hardy Dr. A. S. Fraser and Dr. B. F. Short), 849
Pila globosa (Swainson) : Uricotelism in the Common Indian Apple-Snail (Dr. M. B. Lal and B. B. Saxena), 1024
Piliferous Layer in the Lupin : Secondary (Miss P. A. Lush), 127
Pisum sativum (L.) . Occurrence of Gamma-Amino-Butyric Acid in Extracts of, and in the Honeydew of *Myzus circumflexus* (Buck.), (J. L. Auclair and J. B. Maltais), 1114
Pituitary (Avian) : The Structure and Development of the, from a Comparative and Functional Viewpoint (Karl Georg Wingstrand), *review* by Dr. A. J. Marshall, 553
Pituitary Gland . Posterior (Society for Endocrinology Symposium on), 197
Place : The Old (C. C. Vyvyan), *review*, 818
Placenta (Human) : Adrenal Cortical Hormones in (Constance de Courcy, *Prof. C. H. Gray and J. Barbara Lunnon*), 494
Plakalbumin   Stepwise Degradation of the Peptides liberated in the Transformation of Ovalbumin to (Martin Ottesen and Albert Wollenberger), 801

Plakalbumin-forming Enzyme from *Bacillus subtilis* : Preparation of Crystals containing the (A. V. Guntelberg and M. Ottesen), 802
Planck Medal for 1952 of the Association of German Physics Institutes awarded to Prof. P. A. M. Dirac, 608, 695
Planets : Tidal Forces in the Sun's Corona due to (K. G. Meldahl), Part 3, 482
Planets (Terrestrial) . Cores of (Prof. K. E. Bullen), 363
Planets and Sunspots, 482
Plant Breeders' Conference : Fifth (Agricultural Research Council), 307
Plant Cells · Pectinase Technique for Isolating (J. Chayen), 1070
Plant Debris : Colonization of, by *Coprinus* Species in Soils (E. J. Chinnayya), 252
Plant Embryos *in vitro* : A New Technique for the Sterile Culture of (Pearl Stokes), 242
Plant Growth Substances Text-Book of, *review* by Dr. J. A. Bentley, 510
Plant Nitrogen · Quantitative Paper Chromatography of (J. F. Thompson and F. C. Steward), 828
Plant Protein Feeds · A Difference in *in vitro* Pancreatic Digestion between Animal and (Dr. A. Bondi and Mrs. Yehudith Birk), 673
Plant Raw Materials, 956
Plant Species · Stages in the Evolution of (Jens Clausen), *review* by Dr. W. B. Turrill, 385
Plant Species in Scotland : A New Circumpolar, 783
Plant Taxonomy : Modern, *review* by Dr. W. B. Turrill, 385
Plant Viruses, Old and New, *review* by Dr. K. M. Smith, 1087
Plant Viruses and Virus Diseases (F. C. Bawden), third edition, *review* by Dr. K. M. Smith, 1087
Plants : Disease in (the late Dr. Neil E. Stevens and Prof. Russell B. Stevens), *review* by Dr. S. G. Jones, 860
  Male Sterile, by Chemical Treatment (Dr S. Rehm), 38
  Mineral Nutrition of (edited by Emil Truog), *review* by Dr. G. Bond, 176
  Morphogenesis in (Prof. C. W. Wardlaw), *review* by Prof. Edmund W. Sinnott), 990
  Occurrence of Malonic Acid in (Miss L. E. Bentley), 847
  Solanaceous Alkaloids in Normal and Grafted (G M. James and B. H. Thewlis), 1002
Plants (Cultivated) : The Origin, Variation, Immunity and Breeding of (Selected writings of N. I. Vavilov), translated from the Russian by Dr. K. Starr Chester, *review* by Prof. S. C. Harland, 48
  Vavilov on, *review* by Prof. S. C. Harland, 48
Plants (Higher) : Anatomy of Metabolism in (Prof. Meirion Thomas), 399
Plants in Europe : Protection of, 143
Plants and Invertebrates . The Action of Hormones in (edited by Kenneth V. Thimann), *review* by Dr. Arthur W. Galston, 724
Plasma Albumin . Reaction of Vitamin A Aldehyde with (K. Rajagopal and P. K. Datta), 370
Plasma Thromboplastin (Dr. Rosemary Biggs), 280
Plasticity of Materials (British Society of Rheology Conference on), 875
Plastics Industry Education Fund, 144
Plastics and Allied Industries : Postgraduate Research Scholarships in the Textile, (Courtauld's Scientific and Educational Trust Fund Awards), 346
Podocarpus and *Dacrydium* : Chemical Differentiation of the Genera (the late C. W. Brandt and B. R. Thomas), 1018
Podzol Formation : Translocation of Iron in (C. Bloomfield), 540
Point of View : The Worker's (Acton Society Trust, Nationalized Industry Series 11), 812
Poison (Dart) · Pharmacological and Toxicological Actions of, used in Malaya (Robert Chun Yu Lin), 416
Poisoning of Oxide Cathode Emission by Oxygen (Dr. A. A. Shepherd), 839
Polarization of the Protons produced in the D—D Reaction · Evidence for the (G. R. Bishop, G. Preston, J. M. Westhead and H. H. Halban), 113
Polarization Field and the Acoustic Modes of Oscillation of Alkali Halide Crystals (Sir K. S. Krishnan and S. K. Roy), 159
Political Theory . Principles of Social and (Sir Ernest Barker), 1
Pollen Grains (Tertiary) . Identification of, with those of New Guinea and New Caledonian Beeches (Dr. Isabel C. Cookson), 127
Polyatomic Molecules · Electronic Orbitals, Shapes and Spectra of (Dr. A. D. Walsh), 974
Polygalacturonase : Enzymic Degradation of Pectic Acid and the Complex Nature of (Audrey Ayres, J. Dingle, A. Phipps, W. W. Reid and G. L. Solomons), 834
Polyhedral Virus Diseases : Cytoplasmic (N. Xeros), 1073
Polyhedral Viruses · Transmission of, between different Insect Species (Dr. Kenneth M. Smith and N. Xeros), 492
Polymer Science Seminar on (University College, London), 406
Polymerization . Relation between Intrinsic Viscosity and Degree of (W. G. Harland), 667
Polymers (Linear High) : Irradiation of (Dr. K. Little), 1075
Polymers (Vinyl) : Self-branching of (J. C. Bevington, G. M. Guzman and Prof. H. W. Melville), 1026
Polynucleotides from Deoxyribonucleic Acids (Dr. J. D. Smith and Dr. Roy Markham), 120
Polypeptide (Synthetic) . Behaviour of a, analogous to Protein Denaturation (Dr. A. Elliott), 1066
Polypeptide produced by *Bacillus subtilis* : An Antifungal (J. Babad, A. Pinsky, R. Turner-Graff and N. Sharon), 618
Polysaccharides of Medical Importance (Prof. M. Stacey), 690
Polystictus (=*Polyporus*=*Trametes*) *cinnabarinus* (Jacq.) Fr. . Identity of, with *Polystictus sanguineus* (L.) Fr., (Prof. S. R. Bose), 1020
Polystictus sanguineus (L.) Fr.: Identity of *Polystictus* (=*Polyporus*=*Trametes*) *cinnabarinus* (Jacq.) Fr. with (Prof. S. R. Bose), 1020
Polyuronide Hemicelluloses from Jute : Viscosity of Sodium Salt of (Dr. P. K. Saha), 281
Pond (London) : Trematode Life-Cycle enacted in a (Dr. Ben Dawes), 72
Popular Interests in Science, 404
Population and Food . World, *review* by Miss M. W. Grant, 259
Pore-Size Distribution in Porous Metal Bodies : Determination of the (Dr. P. R. Marshall), 761
Porosity in Copper–Nickel Alloys · Lattice Vacancies and (Dr. E. C. Ellwood), 580
Porosity and Compaction of Clayey Deposits: Natural Moisture-content, (Prof. P. G. H. Boswell), 156
Porous Metal Bodies · Determination of the Pore-Size Distribution in (Dr. P. R. Marshall), 761
Porphobilinogen : Isolation of, from the Urine of a Patient with Acute Porphyria (R. G. Westall), 614
Porphyria (Acute) : Isolation of Porphobilinogen from the Urine of a Patient with (R. G. Westall), 614
Porphyrin Pigments : Ionophoretic Separation of (Dr. S. C. Papastamatis and Dr. J. E. Kench), 33
Potassium-deficient Barley · Occurrence of Putrescine in (F. J Richards and R. G. Coleman), 460
Potato Root Eelworm, *Heterodera rostochiensis* Wollenweber : Resistance to the (Dr. C. Ellenby), 1016
Potato Shoot Apex : Regeneration of the (I. M. Sussex), 755
Potato Tubers : Some Electrical Differences between Healthy and Virus-infected (C. G. Greenham, D. O. Norris, R. D. Brock and A. M. Thompson), *erratum*, 308
Pouch (Blind Self-filling) : Absorption from Intestine of Rats with (D. W. Taylor), 81
Poverty—Ten Years after Beveridge (Political and Economic Planning Broadsheet, No. 344), 481
  Social Insurance and the Problems of, 481
Powder Metallurgy · Treatise on (Dr. Claus G. Goetzel), Vol. 3, *review* by H W. Greenwood, 817
Power · The Problem of (Lord Radcliffe of Werneth), 1
Power Sources in Arid Zones (Advisory Committee on Arid Zone Research of Unesco Meeting), 523
Precipitates (Crystalline) . Ageing of (Prof. I. M. Kolthoff), 599
Precursor : Biosynthesis of Vitamin C and a New (Prof. M. C. Nath, R. P. Chitale and Miss Bhavani Belavady), 545
Pregnancy of Malayan Forest Rats : Moonlight and the (J. L. Harrison), 73
Present Question Conference on Freedom and Responsibility, 217
Preservation of Geological Sites—Bilston Glen, 855
Preservation of a Saxon Wooden Bucket (Dr. A. A. Moss), 1002
President's Prize of the British Institution of Radio Engineers awarded to G. R. Baswick, 308
Primitive Medicine at the Wellcome Historical Museum, 273
Principles Governing the Amount of Experimentation in Developmental Work (Dr. F. Yates), 138
Printing : The Chemical Technology of Dyeing and (Dr. Louis Diserens), Vol. 2, translated and edited from the second German edition by Paul Wengraf and Herman P. Baumann, *review* by Dr. S. M. Neale, 178
Printing Industry : Training of Designers for the (London and Home Counties Regional Advisory Council), 18
Prism and Lens Making (F. Twyman), second edition, *review* by H. W. Lee, 553
Probability · Logical Foundations of (Prof. Rudolf Carnap), *review* by Prof. Harold Jeffreys, 507
Problem-solving Situation : Some Speed, Error and Difficulty Relationships within a (W. D. Furneaux), 37, *erratum*, 269
Proceedings of the Bihar Academy of Agricultural Sciences, No. 1, 563
Procter Memorial Lecture of the Society of Leather Trades' Chemists (Prof. J. B. Speakman), 1054
Productivity of Hot and Cold Deserts : Biology and (Institute of Biology Symposium on), 951
Progesterone in Body Fluids (D. G. Edgar), 543
Progesterone in the Mating Behaviour of the Ewe : Role of (T. J. Robinson), 373
Proline and Hydroxyproline in Leaves (Prof. K. V. Giri, K. S. Gopalkrishnan, A. N. Radhakrishnan and C. S. Vaidyanathan), 579
Prominence Activity and the Sunspot Cycle (Dr. R. Ananthakrishnan), 156
Properties : Anomalous, in Quartz (Ian McDowall and W. Vose), 366
Prospecting by Geophysical Methods (European Association of Exploration Geophysicists Conference on), 230
Protection of Cotton in Peace and War, *review*, 594
Protection from Radiation : Mode of Action of Agents giving (Dr. P. Alexander and Dr. M. Fox), 1022
Protein Crystal Densities · Determination of (Dr. Barbara W. Low and Frederic M. Richards), 412
Protein Denaturation : Behaviour of a Synthetic Polypeptide analogous to (Dr. A. Elliott), 1066
Protein Feeds (Animal and Plant) A Difference in *in vitro* Pancreatic Digestion between (Dr. A. Bondi and Mrs. Yehudith Birk), 673
Protein Fibres : The Reactivity of—some Analogies between Keratin and Collagen (Prof. J. B. Speakman), 1054
Protein Monolayers. Tanning of Fatty Acid and, by Metal Ions (Cr, Al, Fe and Cu) (Dr. J. H. Schulman and M. Z. Dogan), 31
Protein Structure : Infra-Red Dichroism and (Dr. R. D. B. Fraser and Dr. W. C. Price), 490
Proteins . A New Method for Acetylating (Dr. J. Baddiley, Dr. R. A. Kekwick and Dr. E. M. Thain), 968
  Biogenesis of (Symposium on, at the Second International Congress of Biochemistry), 443
  Chemistry and Biology of (Prof. Felix Haurowitz), *review* by Dr. R L. M. Synge, 6
  'Double Fronting' in Paper Chromatography of (Hans G. Boman), 703
  Facts and Speculations about, *review* by Dr. R. L. M. Synge, 6
  Hormones related to (Symposium on, at the Second International Congress of Biochemistry), 443
  The Physical Chemistry of (Faraday Society General Discussion on), 518
  The Structure of (Royal Society Discussion on), 53
Proteins (Serum) . Paper Electrophoresis of (B. Levin and V. G. Oberholzer), 123
Protons produced in the D—D Reaction Evidence for the Polarization of the (G. R. Bishop, G. Preston, J. M. Westhead and H. H. Halban), 113
Protoporphyrin in *Chlorella* : Precursors of (Lawrence Bogorad and S. Granick), 321
Protozoa : Growth of (New York Academy of Sciences and the Society of Protozoologists Conference on), 406
  Reference List of Cultures of (Society of Protozoologists), 483
Pseudo-Cholinesterase of Brain (Prof. B. Mendel and D. K. Myers), 928
Pseudomonas hydrophila · Phosphorylation of Xylose by Extracts of (Dr. Rolf M. Hochster and Dr. R. Wade Watson), 357
Psilomelane, $(Ba,H_2O)_2Mn_5O_{10}$: Role of Water in the Structure of (A. D. Wadsley), 973
Psychical Research Dissected, *review* by Dr. E. J. Dingwall, 176
Psychology : International Congress of, 145

Psychology at Manchester, 440
Psychology of the Occult (D. H. Rawcliffe), *review* by Dr. E. J. Dingwall, 176
Psychology of Pierre Janet (Elton Mayo), *review* by Prof. John Cohen, 592
Psychology and Art of the Blind (Prof. G. Révész), *review* by Prof. John Cohen, 815
Pteridin Content of their Wings : Sex in *Pieris rapae* L. and the (Dr. Katashi Makino, Kiyoo Satoh, Masahiko Koike and Naomichi Ueno), 933
Pteridophyte : A Ligulate, from the Lower Coal Measures of Bacup, Lancashire (Dr. H. Duerden and A. S. Wright), 41
Ptilinus pectinicornis L. Symbiosis in (E. A. Parkin), 847
Public Expenditure : The Control of—Financial Committees of the House of Commons (Dr. Basil Chubb), 171 ; *review* by R. Brightman, 337
Public Health Engineering : Bursaries for Postgraduate Study and Research in (Division of Medicine and Public Health of the Rockefeller Foundation), 189
Pullet (Œstrogenized Immature) Vitamin A Ester and Vitamin A Alcohol in the Serum of the (V. E. Gardiner, W. E. Phillips, W. A. Maw and Prof. R. H. Common), 80
Pulp and Paper Industries : United States, 965
Pulping of Illuk Grass (*Imperata arundinacea*) by Soda and Mono-Sulphite Processes (Chattar Singh and Dr. S. R. D. Guha), 27
Pulps for Writing and Printing Papers from the Castor Oil Plant *Ricinus communis* (Dr. R. V. Bhat and Narendra S. Jaspal), 28
Pumice from Denmark : Sub-Fossil Hekla (Prof. A. Noe-Nygaard), 227
Pure Culture : Growth-Factor Requirements of *Pellicularia koleroga* Cooke in (K. T. Mathew), 889
Purification of Cytochrome c (Dr. E. Margoliash), 1014
Purification of a Lipid Material ('Cord Factor') obtained from Young Cultures of Tubercle Bacilli (E. Sorkin, H. Erlenmeyer and H. Bloch), 124
Purines : Transaminases for Pyridoxamine and (Prof. Carolyn F. Gunsalus and Joseph Tonzetich), 162
Putrescine in Potassium-deficient Barley : Occurrence of (F. J. Richards and R. G. Coleman), 460
Pyridine Extraction of Coal : Nature of the Solution obtained by (E. Boult, H. R. Thirsk and H. E. Blayden), 317
Pyridoxal Derivatives in Transamination (Dr. J. Baddiley), 711
Pyridoxamine and Purines : Transaminases for (Prof. Carolyn F. Gunsalus and Joseph Tonzetich), 162
Pyrimidine Base from Bacteriophage Nucleic Acids A New (Dr. G. R. Wyatt and Dr. S. S. Cohen), 1072
Pyrite . Screw Dislocations in (A. F. Seager), 425
Pyrolysis of Dissolved Nitrocellulose (R. D. Smith), 844
Pyruvate . Role of Sulphydryl Groups in the Oxidation of (Dr. E. C. Slater), 970

QUALITATIVE Organic Analysis : A Text-Book of Practical Organic Chemistry, including (Dr. Arthur I. Vogel), second edition, *review* by Prof. J. W. Cook, 727
Quantitative Chemical Analysis . A Basic Course in the Theory and Practice of (Prof. George L. Clark, Prof. Leonard K. Nash and Prof. Robert B. Fischer), *review*, 727
Quantitative Spot Test on Filter Paper and Examples of its Application (Tatsuo Kariyone, Shuichi Shimizu and Dr. Yohei Hashimoto), 422
Quantum Mechanics of Particles and Wave Fields (Prof. Arthur March), *review* by Prof. G. Temple, 727
Quantum Mechanics of Valence, *review* by Prof. Linus Pauling, 384
Quartz . Anomalous Properties in (Ian McDowall and W. Vose), 266
  Screw Dislocations in (B. T. M. Willis), 115
α-Quartz . Abnormal Thermal Behaviour of, from some New Zealand Soils (M. Fieldes), 366
Quaternaries . Factors Governing the Adaptation of Bacteria against (R. Fischer and Dr. P. Larose), 715
Quaternary Fission of Uranium-235 : Possibility of the (Prof. E. W. Titterton), 794
Quercus sessiliflora (*Q. petraea*) : Ecology of (P. Dineur), 652
Question, Vol. 4, No. 2, Freedom and Responsibility? (Prof. H. D. Lewis, H. J. Blackham, Dr. J. Bronowski and Wells Coates), 217

RABBIT : Myxomatosis in Australia—a Step towards the Biological Control of the (F. N. Ratcliffe, K. Myers, B. V. Fennessy and J. H. Calaby), 7
Rabbit Antibody (Homologous) : Inhibition of Lysine Decarboxylase from *E. coli* by (Arthur F. Howe and Prof. Henry P. Treffers), 123
Rabbit Eggs (Fertilized) : Behaviour of, exposed to Glycerol and to Low Temperatures (Dr. A. U. Smith), 374
Rabbit Repellents (H. V. Thompson and C. J. Armour), *correction*, 442
Rabbit's Skin : Survival of Adrenal Gland Homografts in the (Dr. D. A. Darcy), 805
Rabbits . Distribution of Dextran in the Tissues of (Bengt H. Persson), 716
Rabies (Experimental) Terramycin in the Treatment of, in Mice (M. A. Haseeb), 983
Race Mixture Disadvantages of (Prof. R. Ruggles Gates), 896
Race Problems (British Social Biology Council Conference on), 784
Racemic Substances : New Procedures for Resolution of (H. M. Powell), 155
Radar : Application of, to Meteorology—Conference in Montreal (R. F. Jones), 1004
Radar Melting-Band Cross-polarization of the (Ian C. Browne and N. P. Robinson), 1078
Radar Weather Conference : Third, 1004
Radiation 'Detectivity', the Reciprocal of Noise Equivalent Input of (R. Clark Jones), 937
  Mode of Action of Agents giving Protection from (Dr. P. Alexander and Dr. M. Fox), 1022
Radiation Chemistry (Faraday Society General Discussion on), 194
Radicals (Free) : Reactivity of (Faraday Society Discussion in Toronto), 819
  Stabilization of, its Importance in Reaction Kinetics (Prof. Zoltán G. Szabó), 246
Radicals (Phenyl) Reactions of, in Solution and in the Gaseous Phase (M. T. Jaquiss and Dr. M. Szwarc), 312
Radii of Curvature Evaluation of Small, using the Light-Profile Microscope (Prof. S. Tolansky and M. Omar), 758
Radio Echoes and Lightning (V. G. Miles), 365
Radio-Frequency Allocations in Europe, 185
Radio-Frequency Radiation from Tycho Brahe's Supernova (A.D. 1572) (R. Hanbury Brown and C. Hazard), 364
Radio Observations of the Solar Eclipses of September 1, 1951, and February 25, 1952 (J.-F. Denisse, E. J. Blum and J.-L. Steinberg), 191
Radio Sources (Discrete) : Apparent Angular Sizes of—Observations at Jodrell Bank, Manchester (R. Hanbury Brown, R. C. Jennison and M. K. Das Gupta), 1061 ; Observations at Sydney (B. Y. Mills), 1063 ; Observations at Cambridge (F. G. Smith), 1065
Radio Star . Occultation of a, by the Solar Corona (K. E. Machin and F. G. Smith), 319
Radio Waves of Frequency 1·42 Mc./s. : Weak Echoes from the Ionosphere with (S. Gnanalingam and K. Weekes), 113
Radioactive Isotopes Luminescence of Aqueous Solutions of, and the Cerenkov Effect (Dr. E. H. Belcher), 571
Radioactive Iodine (^{131}I) British Standard of (Dr. E. C. Bullard), 916 ; (Dr. Henry Seligman and John L. Putman), 917
Radioactive Isotopes : Technique of handling and using (Course of instruction at the Ministry of Supply's Isotope School at Harwell), 694
Radioactive Tracer : Use of, in the Study of Insect Populations (Lepidoptera), (Dr. H. B. D. Kettlewell), 584
Radioactive Tracers Demonstration by, of the Adsorption of Cations by Metals (Prof. J. Palacios and A. Baptista), 665
Radioactivity Application of, to Mineral Dressing (Prof. A. M. Gaudin), 656
  Beta, 514
  Beta- and Gamma-ray (Netherlands Physical Society, the International Union of Pure and Applied Physics, and Unesco, Conference on), 229
Radioautography . Detection of Radiophosphorus in Cells and Spores of Fungi by (A. M. Adams and J. J. Miller), 239
Radiochemical Method Autoradiography of Metal Surfaces using a (E. Rabinowicz), 1029
Radiography Gamma-Ray Sources for (Industrial Radiology Group of the Institute of Physics Memorandum on), 186
Radiophosphorus in Cells and Spores of Fungi Detection of, by Radioautography (A. M. Adams and J. J. Miller), 239
Radium-D γ-Rays of (Dr. George T. Ewan and Dr. M. A. S. Ross), 760
Rain-Makers : Aboriginal (Frederick D. McCarthy), 26
Ramsay Memorial Fellowships, 60
Rat : Oxidation of Thiophosphate Insecticides in the (D. K. Myers, Prof. B. Mendel, H. R. Gersmann and Prof. J. A. A. Ketelaar), 805
Rat Heart Sarcosomes : Permeability of Isolated (Dr. K. W. Cleland), 497
Rat Liver . Glucose-6-Phosphate Dehydrogenase Activity of (Dr. G. E. Glock and P. McLean), 119
Rat Ovary Growth of, in Tissue Culture (Jean I. Scott), 208
Rat Pancreas Rapid Restitution of the, following Acinar Cell Necrosis subsequent to Ethionine (Dr. Patrick J. Fitzgerald and Dr. Mario Alvizouri), 929
Rats Toxicity of Dextran in (T. Edlund, B. Lofgren and L. Vali), 125
Rats (Malayan Forest) . Moonlight and the Pregnancy of (J. L. Harrison), 73
Rats (Normal) : Effect of Cortisone on the Blood Pressure of (C. Bertazzoli, Prof. C. Cavallero and G. Sala), 43
Rats with Blind Self-filling Pouch Absorption from Intestine of (D. W. Taylor), 81
Rats' Incisor Teeth Macrophages in the Periodontal Tissues of (Prof. J. T. Irving), 573
Reaction (D—D) Evidence for the Polarization of the Protons produced in the (G. R. Bishop, G. Preston, J. M. Westhead and H. H. Halban), 113
Reaction ^{7}Li$(d,n)^{8}$Be Angular Distribution of the Neutrons from the (Prof. B. Trumpy, T. Grotdal and A. Graue), 1118
Reaction between Dichromate and Diphenylcarbazide Mechanism of the (Monisha Bose), 213
Reaction between Diethyl Peroxide and Nitric Oxide (H. N. Mortlock and Dr. D. W. G. Style), 706
Reaction of Vitamin A Aldehyde with Plasma Albumin (K. Rajagopal and P. K. Datta), 370
Reaction Kinetics . Stabilization of Free Radicals, its Importance in (Prof. Zoltán G. Szabó), 246
Reaction Theory of Morphogenesis : A Diffusion, 955
Reactions Autoxidative—their Chemistry, Mechanisms and Catalysis by Metal Salts (Prof. C. E. H. Bawn), 653
Reactions (Transamination) . A Simple Paper Chromatographic Method for the Study of (Dr. K. V. Giri, A. N. Radhakrishnan and C. S. Vaidyanathan), 1025
Réactions dans l'état solide (Colloques Internationaux du Centre National de la Recherche Scientifique, 10, Paris, Octobre 1948), *review* by Prof. J. R. Partington, 944
Reactions of Phenyl Radicals in Solution and in the Gaseous Phase (M. T. Jaquiss and Dr. M. Szwarc), 312
Reactivity of Free Radicals (Faraday Society Discussion in Toronto), 819
Reactivity of Protein Fibres—some Analogies between Keratin and Collagen (Prof. J. B. Speakman), 1054
Re-afforestation Regeneration and, 652
Reagent (Anthrone) Determination of Yeast Carbohydrates with the (W. E. Trevelyan, R. S. Forrest and J. S. Harrison), 626
Reagent (Colour) Ultra-Violet Papyrography—an Automatic Analytical Apparatus using Filter Paper without a (Dr. Yohei Hashimoto and Itsuhiko Mori), 1024
Reagents (Mutagenic) : Site of Action of—Nitrogen Mustards (Miss M. J. Ord and Prof. J. F. Danielli), 921 ; X-Rays (Dr. E. B. Harriss, Dr. L. F. Lamerton, Miss M. J. Ord and Prof. J. F. Danielli), 922
Reciprocal of Noise Equivalent Input of Radiation 'Detectivity', the (R. Clark Jones), 937
Reclaiming Land for Agriculture (Moses Griffith, J. F. H. Thomas and R. Line), *review* by G. V. Jacks, 858
Recoil Atoms from an Adjacent Phase Decomposition of Organic Matter by (D. F. Sangster and J. Wright), 368
Red-Cell Volume in the Tropics : Packed (Dr. G. R. Wadsworth), 851
Red Cells (Human) : Agglutination Reactions in, fragmented by Heat (Ruth Ponder and Dr. Eric Ponder), 928
Rede Lecture (Sir Russell Brain), 58

- Rediscovery of the Ophiuroid Genus *Ctenamphiura* Verrill (Dr. H. Barraclough Fell), 327
- Reduction of Tropinone with Lithium Aluminium Hydride (Dr. Refat Mirza), 630
- Refection in the Common Shrew (Peter Crowcroft), 627
- Refinery Production in Great Britain during 1951: Petroleum Consumption and (Petroleum Information Bureau), 268
- Refining of Metals: Principles of the Extraction and (Institution of Metallurgists), 405
- Refugees: Indigent Aliens and (Economic and Social Council of the United Nations Resolution on), 267
- Regeneration of the Potato Shoot Apex (I. M. Sussex), 755
- Regeneration and Re-afforestation, 652
- Regression of Mouse Tumours: Relative Biological Effectiveness of Betatron and Conventional X-Radiation on the (Dr. T. P. King, Dr. H. E. Jones and Prof. L. B. Jaques), 752
- Reith Memorial Lectures, 1951 (Lord Radcliffe of Werneth), 1
- Relativistic Theory of a Rigid Body (Prof. R. W. Ditchburn and O. S. Heavens), 705
- Relativity (Special): Rigid-Body Motions in (G. H. F. Gardner), 243
- Relativity and Indeterminacy (Dr. G. W. Scott Blair), 582; (C. O. Hines), 582; (H. Bondi and T. Gold), 582
- Reporting Research in Education (Stephen Wiseman), 607
- Reporting Science, 381
- Reproduction in the Minnow: Influence of Thiourea on (Prof. E. J. W. Barrington and A. J. Matty), 105
- Research: Essay Competition, 1049
- Research: Arid Zone (Dr. H. G. Thornton), 300; (Prof. S. Goldstein), 300
  - Desert (Research Council of Israel in co-operation with Unesco International Symposium on), 300
  - Foot-and-Mouth Disease, in Great Britain, 908
  - Geophysical, aboard the R.R.S. *Discovery II*, 17
  - Government, in Australia—Commonwealth Scientific and Industrial Research Organization, 565
  - Instructional Film (C. Denis Pegge), 962
  - Lectures on, in the Universities of the United States (American Embassy and the United States Educational Commission in the United Kingdom Grants to British scholars for), 145
  - The Microscope in Industry and (W. Watson and Sons, Ltd., Exhibition on), 348
  - Paper Pulp, at the Dehra Dun Research Institute, 27
  - Scientific, and Man-power Problems, 129
  - Selection and Training for, 941
- Research 1951: Chemistry, 1109
- Research (Arctic or Sub-Arctic): Fellowship and Scholarships for work on (McGill University and the Arctic Institute of North America), 695
- Research (Cancer): Progress of, 515
- Research (Cement): Laboratories for, 270
- Research (Food): Advances in (edited by E. M. Mrak and George F. Stewart), Vol. 3, *review* by A. T. Parsons, 680
- Research (Geological): Some Aspects of, and their Practical Application (Dr. J. E. Richey), 394
- Research (Hormone): Recent Progress in (Proceedings of the Laurentian Hormone Conference), Vol. 5 (edited by Gregory Pincus), *review*, 858
- Research (Industrial): Secrecy and (Dr. C. E. Kenneth Mees), 972
  - Selection, Training and Use of Personnel in (Proceedings of the Second Annual Conference on Industrial Research, June 1951, sponsored by the Department of Industrial Engineering, Columbia University, edited by David B. Hertz and Albert H. Rubenstein), 941
- Research (Nutritional): Present Problems in (International Union of Nutritional Sciences Symposium on), 442
- Research at Edinburgh on Cancer, 404
- Research in the University: Applications of Photography to (Scientific and Technical Group of the Royal Photographic Society Symposium on), 348, 879
- Research at the University of Birmingham during 1950–51, 228
- Research in Analytical Instrumentation (Dr. R. H. Muller), 599
- Research in Chemistry: Grants for (Research Fund of the Chemical Society), 145
- Research on the Constitution of Alloys (Constitution of Alloys Group of the British Iron and Steel Research Association), 305
- Research in Education: Reporting (Stephen Wiseman), 607
- Research Developments by British Thomson-Houston Co., Ltd., 483
- Research Dissected: Psychical, *review* by Dr. E. J. Dingwall, 176
- Research Effort in Britain: Distribution of, 465
- Research Fellowships: Engineering (British Thomson-Houston Co., Ltd.), 59
  - Wellcome Pharmaceutical, awarded to J. Thomas and G. L. Willey, 346
- Research Grants (National Science Foundation, Washington), 484
- Research Grants for the Department of Anatomy, Oxford, 870
- Research Levy: Wool Industry, 267
- Research Scholarship of the Pharmaceutical Society awarded to L. E. Coles, 346
- Research Scholarships: Postgraduate, in Textile Technology (Courtauld's Scientific and Educational Trust Fund Awards), 346
  - Postgraduate, in the Textile, Plastics and Allied Industries (Courtauld's Scientific and Educational Trust Fund Awards), 346
- Research Studentships in Ecology (Nature Conservancy Awards for 1952), 524
- Research Techniques in Physics: New (Academia Brasileira de Ciencias and Unesco Centro de Cooperación Científica para América Latina Symposium on), 19, 700
- Research and Development: Colonial (Bernard Braine), 871
- Research and Development (Scientific): Manpower in, 505
- Research and Development in the British Industry, a Survey of Expenditure on Industrial Research and Development in the Year 1950–51 (Industrial Research Committee of the Federation of British Industries), 465
- Research and Industry: British Electronic Instruments in (Scientific Instrument Manufacturers' Association of Great Britain Symposium on), 877
- Researches on Biophysics: Some (edited by Y. Asami), 482
- Resin Content of the Hop Cone: Influence of Mineral Nutrition on the (F. C. Thompson and Dr. A. H. Burgess), 890
- Resistance to Change (British Association for the Advancement of Science, Section J (Psychology), Discussion on), 688
- Resistance to Change in Farming (British Association for the Advancement of Science, Sections J (Psychology) and M (Agriculture), Symposium on), 688
- Resistance to Colchicine in a Strain of *Trichomonas vaginalis*: Acquired (Prof. S. Adler, A. Back and A. Sadovsky), 930
- Resistance to *Heterodera rostochiensis* in *Solanum tuberosum*, var. *andigenum*: Genotypical Background of (Dr. H. J. Toxopeus and C. A. Huijsman), 1016
- Resistance of *Lemna minor* to the Phytotoxic Action of 2 : 4 Dichlorophenoxyacetic Acid: Effects of Preliminary Treatment on the Subsequent Variation in the (R. C. Robertson-Cuninghame and Prof. G. E. Blackman), 459
- Resistance to the Potato Root Eelworm, *Heterodera rostochiensis* Wollenweber (Dr. C. Ellenby), 1016
- Resolute, Cornwallis Island, Canada: Permafrost Drilling and Soil-Temperature Measurements at (Andrew Thomson and P. C. Bremner), 705
- Resolution of Racemic Substances: New Procedures for (H. M. Powell), 155
- Resonance of Uranium-238: Determination of Neutron Resonance Parameters from Measurements of the Absorption Integral—Application to the Main (G. v. Dardel and R. Persson), 1117
- Resonance Parameters (Neutron): Determination of, from Measurements of the Absorption Integral—Application to the Main Resonance of Uranium-238 (G. v. Dardel and R. Persson), 1117
- Responsibility: Authority and, 1
  - Freedom and (Present Question Conference on), 217
- Resuspension of Dow Latex '580G' by Ultrasonics (P. Hatfield, H. W. Emerton and P. E. Wright), 797
- Reticulin: Nature of (Dr. K. Little and H. Kramer), 499
- Retinal Colour Processes caused by Intermittent White Light (Prof. Koiti Motokawa and Mituru Ebe), 79
- Retinal Image: Vision with a Stabilized (Prof. R. W. Ditchburn and B. L. Ginsborg), 36
- Reversal of the Heart-beat in Tunicates (Dr. R. H. Millar), 851
- Reversal of the Molecular Set in Keratin (J. Sikorski), 275
- Rex (Vestigial and): A New Linkage in the House Mouse—(Donald Michie), 585
- Rheology: Second International Congress on, 487
- Rhinobatidae: Hyoid Arch of (A. R. Hamdy), 166
- *Rhizobium meliloti*: Synthesis of Vitamin B_{12} by (M. O. Burton and A. G. Lockhead), 913
- Richtmyer Memorial Lecture of the American Association of Physics Teachers (Prof. E. Fermi), 612
- Rickettsiae: Nucleic Acids of (Dr. G. R. Wyatt and Dr. S. S. Cohen), 846
- Rigid Body: Relativistic Theory of a (Prof. R. W. Ditchburn and O. S. Heavens), 705
- Rigid-Body Motions in Special Relativity (G. H. F. Gardner), 243
- Road Engineers: Soil Mechanics for (Department of Scientific and Industrial Research: Road Research Laboratory), *review* by K. L. Nash, 639
- Roads and Runways: Foundation of Good, *review* by K. L. Nash, 639
- Rockefeller Travelling Fellowships in Medicine (Medical Research Council Awards), 189
- Rodah: Le Mikyas ou Nilomètre de l'Île de (Kamel Osman Ghaleb Pasha), *review* by Dr. H. E. Hurst, 132
- Root-Nodules (Zygophyllaceous and Leguminous): Carbohydratic Fermentation of Bacterial Isolates from (Prof. M. A. Mostafa), 276
- Root Nodules of the Alder (*Alnus*): Free Amino-Acids in the Leaves, Roots and (Prof. Artturi I. Virtanen and Jorma K. Miettinen), 283
- Root Parasites in Loranthaceae (H. S. McKee), 40
- Roots and Root Nodules of the Alder (*Alnus*): Free Amino-Acids in the Leaves, (Prof. Artturi I. Virtanen and Jorma K. Miettinen), 283
- Rosenhain Medal for 1953 of the Institute of Metals awarded to Dr. C. E. Ransley, 1098
- Rostral Extremities of the Sympathetic Trunks (Prof. G. A. G. Mitchell), 533
- Rotational Analyses of the Columbium Oxide Bands (S. Suryanarayana Rao), 670
- Royal Medals for 1952 of the Royal Society awarded to Sir Frederic Bartlett and Prof. C. K. Ingold, 870, 946
- Rubber: Hysteresis in (D. M. Davies), 937
- Rubber Accelerators and Anti-Oxidants on Silica Gel: Chromatography of (Dr. C. A. Parker), 539
- Rumen: Origins of the Volatile Fatty Acids in the (F. V. Gray and A. F. Pilgrim), 375
- Rumen of Cattle: Methane Fermentation in the (W. H. Beijer), 576
- Rumford Medal of the Royal Society awarded to Prof. Fritz Zernike, 826, 946
- Rumford Medals of the American Academy of Arts and Sciences awarded to Prof. Enrico Fermi, Prof. W. E. Lamb, jun., and Prof. Lars Onsager, 954
- Ruminants: Cobalt in the Nutrition of—Response of Cobalt-deficient Sheep to Massive Doses of Vitamin B_{12} (Hedley R. Marston and H. John Lee), 791; Control of Cobalt-deficiency in Sheep by Injection of Vitamin B_{12} (Hedley R. Marston and Richard M. Smith), 792; Influence of Cobalt on the Production of Factors possessing Vitamin B_{12}-like Activity in the Faeces of Sheep (Mary C. Dawbarn, Denise C. Hine and Patricia Hughes), 793
  - Effect of the Percentage of Dry Matter in the Diet on the Dry-Matter Intake in (T. L. Dodsworth and W. H. McK. Campbell), 1128
- Runways: Foundation of Good Roads and, *review* by K. L. Nash, 639
- Russell Effect on Evaporated Metal Films (L. Grunberg and K. H. R. Wright), 456
- Rutherford Lecture of the Physical Society (Prof. R. E. Peierls), 524
- Rye, Barley and Oats: Lysenko's Latest Discovery—The Conversion of Wheat into (Prof. P. Maheshwari), 66

- S-MATRIX: The, 514
- S Waves in the Earth's Inner Core: Detection of (Prof. K. E. Bullen and the Rev. T. N. Burke-Gaffney), 455
- Saccharomyces: Proximity of Genes controlling the Fermentation of similar Carbohydrates in (Prof. Carl C. Lindegren and Gertrude Lindegren), 965
- *Saccharomyces cerevisiae*: Isolation of Triploid (Seymour Pomper), 892
  - Single-spore Cultures of Heterothallic, which mate with both the Tester Strains (Dr. M. Ahmad), 546

Sacred Tradition : Archæology, Folklore and (Prof. E. O. James), 397
Safety of Domestic Electrical Installations (H. W. Swann), 18
Salicylate : Antagonistic Effects of Cortisone and (M. J. H. Smith), 240
Salivary α-Amylase : Action of, on Amylopectin and Glycogen (Dr. W. J. Whelan and P. J. P. Roberts), 748
Salmonella typhi : Variation in *Vi*-Phage II of (Dr. E. S. Anderson and Dr. A. Felix), 492
Salting-out Chromatography of Amino-acids and Peptides in Filter Paper and other Media (L. Hagdahl and Prof. A. Tiselius), 799
Sanitary Regulations : International (Sir Arthur MacNalty), 1107
Santa Elena Peninsula in South-west Ecuador : The Archæology of the (G. H. S. Bushnell), *review* by Miss B. M. Blackwood, 51
Sarcoma (Mouse) : Transplantation of, with Small Numbers of Single Cells (H. B. Hewitt), 622
Sarcosomes (Heart-Muscle) : Stabilization of Oxidative Phosphorylation in (Dr. E. C. Slater and Dr. K. W. Cleland), 118
Sarcosomes (Rat Heart) : Permeability of Isolated (Dr. K. W. Cleland), 497
Satellite : The Artificial (edited by L. J. Carter), 486
Sauerstoff (Gmelins Handbuch der anorganischen Chemie, achte Auflage, System-Nummer 3, Lieferung 2), *review*, 902
Saxon Wooden Bucket : Preservation of a (Dr. A. A. Moss), 1002
Schlesinger (Kathleen) Fellowship (Medical Research Council), 653
Scholarship : Jacob Bell Memorial, of the Pharmaceutical Society awarded to T. M. French, 346
    Manchester Pharmaceutical Association, of the Pharmaceutical Society awarded to R. A. Alcock, 346
    Gabriella Zuccari (University of Padua), 442
    Research, of the Pharmaceutical Society awarded to L. E. Coles, 346
Scholarships (National Research Council of Canada Awards for 1952–53), 19
    Fellowship and, for work on Arctic or Sub-Arctic Research (McGill University and the Arctic Institute of North America), 695
    Postgraduate, in Agricultural subjects (Department of Agriculture for Scotland), 784
    Postgraduate Research, in the Textile, Plastics and Allied Industries (Courtauld's Scientific and Educational Trust Fund Awards), 346
    Postgraduate Research, in Textile Technology (Courtauld's Scientific and Educational Trust Fund Awards), 346
Scholarships in Chemical Engineering (Anglo-Saxon Petroleum Co., Ltd.), 829
Scholarships in Medical Science : French Exchange (Medical Research Council Awards), 189
Scholarships in Naval Architecture and Marine Engineering (Institution of Naval Architecture), 1049
Scholarships in Textiles (Textile Institute), 956
School Child : The Health of the (Report for 1948–49 of the Chief Medical Officer to the Ministry of Education), 111
School Science Teachers : Shortage of, 1083
Schools (Secondary) : The Teaching of Geography in (Geographical Association Memorandum on), 187
Schweizer Flora : Taschenatlas der (Eduard Thommen), zweite Auflage, *review* by Prof. F. E. Weiss, 431
Science : The Ethical Dilemma of (Prof. A. V. Hill), 388
    History of, 186
    The Impact of, on Society (Bertrand Russell), *review* by R. Brightman, 468
    The Integrity of, 379
    Popular Interests in, 404
    Reporting, 381
    The Strategy of (Sir Henry Tizard), 427
Science of Domestic Heating (J. S. Hales), 302
Science and the Christian Man (Canon Charles E. Raven), *review* by Dr. F. Sherwood Taylor, 473
Science in Education : Conception of, 228
Science and an Expanding Agriculture (Sir William Slater), 432
Science of Flames and Furnaces (M. W. Thring), *review*, 769
Science and Foreign Relations (United States Department of State, Publication 3860), 1033
Science in Industry : Application of, 427
Science in Latin America, 306
Science in a Satellite State of the Soviet Union (Society for Freedom in Science, Occasional Pamphlet No. 13), 1049
Science and Society, *review* by R. Brightman, 468
Science in the University of Glasgow, 913
Science Teachers (School) : Shortage of, 1083
Scientific Adventure : The (Prof. Herbert Dingle), *review* by F. I. G. Rawlins, 726
Scientific Equipment for British Laboratories : American, 566
Scientific Freedom and Security, 215
Scientific Institutions and Scientists in Latin America (Unesco Science Co-operation Office for Latin America), Venezuela, Vol. 1, 306 ; Brazil, Vol. 3, 306
Scientific Instruments : Current Literature relating to, 1001
    Descriptive Catalogue of the King George III Collection of (Science Museum), 405
    A Review of, *review* by S. Weintroub, 298, erratum, 784
Scientific Instruments, Journal of (edited by Dr. H. R. Lang), Vol. 28 and Supplement No. 1, 1951, *review* by S. Weintroub, 298, erratum, 784
Scientific Papers : Preparation and Publication of (S. Weintroub), 412
Scientific Papers published in the Middle East (Unesco Middle East Science Co-operation Office), List No. 6, 346
Scientific Periodicals (German Medical and) : Cost of (Dr. W. Bonser and Margaret P. Russell), 446
Scientific Principles of Furnace Technology, *review*, 769
Scientific Progress : Latin American Contribution to—Chemistry, 1948–49 (Unesco Science Co-operation Office for Latin America), 306
Scientific Relations : International, and National Security, 1033
Scientific Research and Development : Man-power in, 505
Scientific Research and Man-power Problems, 129
Scientific Societies : Local—Problems and Responsibilities (J. A. S. Stendall), 401
Scientific Thought through the Ages (Dr. Nazir Ahmad), 340
Scientific and Technical Information for Industry, 827
Scientific and Technical Periodicals published in South-East Asia (Unesco East Asia Science Co-operation Office), 59
Scientist : Copyright and the (Leslie Wilson), 1108
Scientist in Civil Defence : The Place of the (London and South-Eastern Counties Section of the Royal Institute of Chemistry, the Institute of Biology, and the London and Home Counties Branch of the Institute of Physics Discussion on), 456, 957
Scientists in Latin America : Scientific Institutions and (Unesco Science Co-operation Office for Latin America), Venezuela, Vol. 1, 306 ; Brazil, Vol. 3, 306
Scintillation of Stars and the Atmosphere, 305
Scintillation Spectrometer Studies on the Decay Schemes of Silver-110, Antimony-124 and Iodine-131 (S. Almqvist and Sven A. E. Johansson), 583
Scintillation and Atmospheric Seeing (H. E. Butler), 305
Sclerotin in the Cockroach Cuticle : A Lipoprotein Precursor of (S. R. A. Malek), 850
Scopoletin : Effect of, on Indoleacetic Acid Metabolism (W. A. Andreae), 83
Scorpion, *Buthus quinquestriatus* (H. E.) : Development of the Embryonic Coverings in the (Dr. A. Abdel-Wahab), 209
Scorpions : Études sur les (Max Vachon), *review* by T. H. Savory, 511
Scotland : *Diapensia lapponica* in (J. Grant Roger), 783
    Management in (T. H. Hawkins), 65
    Marine Biology in, 311
    Television in Wales and, 481
Screw Dislocations on Electrolytically produced Titanium Crystals : Growth Spirals originating from (M. A. Steinberg), 1119
Screw Dislocations in Pyrite (A. F. Seager), 425
Screw Dislocations in Quartz (B. T. M. Willis), 115
Sea : Oil Pollution of the, 738
Seal (Leopard) : Observations on the Newly Born (K. G. Brown), 982
Seasonal Change in the Humidity Reaction of the Common Earwig, *Forficula auricularia* (Dr. Vilho Perttunen), 209
Seaweed Symposium : International (Institute of Seaweed Research, the University of Edinburgh and the Scottish Marine Biological Association), 478
Second Explosion Limits : Effect of Withdrawal-Rate on (Sir Charles Egerton and D. R. Warren), 420
Secrecy and Industrial Research (Dr. C. E. Kenneth Mees), 972
Secretion of the Blood Group Antigens and the Presence of anti-*O* or anti-*H* in Human Serum : A Relationship between the (Dr. Ruth Sanger), 78
Security : Scientific Freedom and, 215
Security (National) : International Scientific Relations and, 1033
Sedimentary Petrography (Henry N. Milner), third edition, *review*, 511
Sedimentation of Halloysite (Ian McDowall and W. Vose), 368
Seeds (Cereal) : X-Ray and Neutron Mutagenic Effects on, 1112
Seeing (Atmospheric) : Scintillation and (H. E. Butler), 305
Seismic Refraction Experiments in the Pacific (Dr. T. F. Gaskell and J. C. Swallow), 1010
Seismic Refraction Shooting in the Atlantic (M. N. Hill and J. C. Swallow), 738
Seismograms : Principles Underlying the Interpretation of (Dr. Frank Neumann), 102
Selection in Evolution : Stabilizing, *review* by Prof. C. H. Waddington, 680
Self-branching of Vinyl Polymers (J. C. Bevington, G. M. Guzman and Prof. H. W. Melville), 1026
Self-incompatibility in *Narcissus* : Trimorphism and (A. J. Bateman), 496
Seminal Fluid (Human) : Pepsinogen in (Dr. Frank Lundquist and Dr. Hans Henrik Seedorff), 1115
Senility Changes in the Spinal Ganglion Neurones of the Toad, *Bufo regularis* (Dr. Tohamy A. Moussa), 206
Sensitivity of Cress Roots to Indole-Acetic Acid (Dr. Franz Moewus and Liselotte Moewus), 372
Sensitivity of the Human Eye : Accuracy and (Dr. M. H. Pirenne and Dr. E. J. Denton), 1039
Sensory Effects : Energetics of (Dr. J. A. B. Gray), 823
Sepsis and Cortisone (Charles Cook and Charles Smith), 980
Sera : An Improved Electrophoresis Cell for the Analyses of Several, Simultaneously (Dr. A. Polson), 628
Serological Division of *Staphylococcus aureus* Bacteriophages, Group G : A New (Joan E. Rippon), 287
Serological Properties of Human Blood Group *A* and *B* Substances (R. A. Gibbons and Prof. W. T. J. Morgan), 77
Serum (Human) : A Relationship between the Secretion of the Blood Group Antigens and the Presence of anti-*O* or anti-*H* in (Dr. Ruth Sanger), 78
Serum of the Œstrogenized Immature Pullet : Vitamin A Ester and Vitamin A Alcohol in the (V. E. Gardiner, W. E. Phillips, W. A. Maw and Prof. R. H. Common), 80
Serum Albumin Monolayers (Bovine) : Ionization of (M. Z. Dogan and Dr. J. Glazer), 417
Serum 5-Nucleotidase (Dr. T. F. Dixon and M. Purdom), 500
Serum Proteins : Paper Electrophoresis of (B. Levin and V. G. Oberholzer), 123
Serum-free Synthetic Medium : Stimulating Effect of Amino-Acids on the Survival at 37° C. of *Trypanosoma rhodesiense* in a (Dr. J. Williamson and L. M. Rollo), 376
Set (Permanent) : Chemical Mechanism of (Dr. R. S. Asquith and Prof. J. B. Speakman), 798
Settlement in the Overseas Dominions : Aspects of (Prof. R. O. Buchanan), 395
Sex in *Pieris rapae* L. and the Pteridin Content of their Wings (Dr. Katashi Makino, Kiyoo Satoh, Masahiko Koike and Naomichi Ueno), 933
Sex Mechanism in *Coccinia indica* Wight and Arn. (L. S. S. Kumar and S. Vishveshwaraiah), 330
Shapes and Spectra of Polyatomic Molecules : Electronic Orbitals, (Dr. A. D. Walsh), 974
Shear : Miscibility of Liquids Influenced by Rate of (A. Silberberg and Prof. W. Kuhn), 450
Sheep Skin Autografts : Spread of Pigment in (Dr. Margaret H. Hardy, Dr. A. [illegible] Dr. B. F. Short), 849
Shell-form[illegible]chia (G. Owen), 148
Ships : [illegible] in (M. J. Tucker), 657
Sho[illegible] in the Presence of Adenosine Triphos-[illegible]or' on the (J. R. Bendall), 1058
Sh[illegible] (Peter Crowcroft), 627
S[illegible] Accelerators and Anti-Oxidants on

Silica-Glass : Dating the Libyan Desert (Dr Kenneth P. Oakley), 447
Silk : Relations between Small-Angle Interferences of, and the Wax Content (Prof. O. Kratky, E. Schauenstein and A. Sekora), 796
Silkworm Effect of Nitrite on the Nuclear Structure in the (Prof. Kazuo Yamafuji), 126
Silver-110, Antimony-124 and Iodine-131 · Scintillation Spectrometer Studies on the Decay Schemes of (S Almqvist and Sven A. E. Johansson), 583
Silver Films and Dielectric Multiple Films in Interferometry (Dr. D. A. Jackson and K. Kuhn), 455 ; (Dr. A. H Jarrett), 456
Silvicultural Observations in Cut-over Areas in Ajuan, Philippines (T. S. Serevo), 652
Silvicultural Systems (Dr. R. S. Troup), second edition, edited by E. W Jones, *review* by Prof. H. G. Champion, 816
Simulium Larvae : Fish Feeding on (Dr. G Marlier), 496
Single-spore Cultures of Heterothallic *Saccharomyces cerevisiae* which mate with both the Tester Strains (Dr. M. Ahmad), 546
Skin (Human) . Localization of Erythermal Processes caused by Ultra-Violet Light in (P. B Rottier and J. A. M Mullink), 574
Skin Autografts (Sheep) . Spread of Pigment in (Dr. Margaret H. Hardy, Dr. A. S. Fraser and Dr. B. F. Short), 849
Sky : The Night, in August, 145 ; in September, 348 ; in October, 524 ; in November, 738 ; in December, 914 ; in January, 1100
Slide Rules Handbook of (Blundell Rules, Ltd.), 103
Small-angle X-Ray Diffraction Maxima in some Artificial Cellulose Fibres : Occurrence of (D. Heikens, P. H Hermans and A. Weidinger), 369
Smith Memorial Medal of the Royal Australian Chemical Institute awarded to Prof R. J. W. LeFèvre, 1049
Smithsonian Meteorological Tables (prepared by Robert J. List), sixth revised edition, *review* by G. A. Bull, 175
Smoke and the Law (W. R. Hornby Steer), 484
Snail, *Pila globosa* (Swainson), (Common Indian Apple-) Uricotelism in the (Dr. M. B. Lal and B. B. Saxena), 1024
Social Behavior . Mathematical Biology of (Nicolas Rashevsky), *review* by E. Grebenik, 3
Social Insurance and the Problems of Poverty, 481
Social and Political Theory Principles of (Sir Ernest Barker), 1
Society Clinic and, *review* by Prof. John Cohen, 592
  The Impact of Science on (Bertrand Russell), *review* by R. Brightman, 468
  Science and, *review* by R. Brightman, 468
Sociological Bulletin, No. 1 (Indian Sociological Society), 481
Sociology ? Mathematical, *review* by E. Grebenik, 3
Soda and Mono-Sulphite Processes · Pulping of Iluk Grass (*Imperata arundinacea*) by (Chattar Singh and Dr. S. R D. Guha), 27
Sodium in the Body · Relation between Total and Exchangeable (Dr. R. E Davies, H L Kornberg and Dr. G. M. Wilson), 979
Sodium Acetate Agar as a Sporulation Medium for Yeast (R. R. Fowell), 578
Sodium 2,4-Dichlorophenoxy-ethyl-sulphate in the Soil · Fate of (Prof. L. J. Audus), 886
Sodium Salt of Polyuronide Hemicellulose from Jute · Viscosity of (Dr. P. K Saha), 281
Sodium Taurocholate Hæmolytic and Surface Activity of (B. A. Pethica and Dr J H. Schulman), 117
Soil : Fate of Sodium 2,4-Dichlorophenoxy-ethyl-sulphate in the (Prof. L J Audus), 886
Soil (Unsterilized) Production of Gliotoxin in (Joyce M. Wright), 673
Soil Algae · Counting, by Direct Fluorescence Microscopy (Y. T. Tchan), 328
Soil Bacteria · Detoxication of Hormone Herbicides by (Dr H. L. Jensen and H. Ingv. Petersen), 39
  Hydrolysis and Metabolism by, of Benzoyl Derivatives of D- and L-Forms of some Amino-Acids (Prof. Yukio Kameda, Etsuko Toyoura, Hiroshi Yamazoe, Yukio Kimura and Yoshiro Yasuda) 888
Soil Bacteria and Chlamydospore Formation in *Fusarium solani* (C S. Venkat Ram), 889
Soil Bacterium A Bacterial Growth-Factor Synthesized by a (A. G. Lochhead, Margaret O Burton and R. H. Thexton), 282
Soil Fumigant Tainting of Tobacco by a Dichloropropene Dichloropropane (C J. Shepherd), 1073
Soil Mechanics for Road Engineers (Department of Scientific and Industrial Research . Road Research Laboratory), *review* by K L. Nash, 639
Soil Percolation Apparatus for Soils of a High Organic Matter Content Modification of a (T M. B. Payne and P. H. H Gray), 325
Soil Samples · A New Method for Isolating Members of the Acrasieae from (E. D Kitzke), 284
Soil-Temperature Measurements Permafrost Drilling and, at Resolute, Cornwallis Island, Canada (Andrew Thomson and P. C. Bremner), 705
Soils . Colonization of Plant Debris by *Coprinus* Species in (E. J. Chinnayya), 252
  Inactivation of DDT by (A B. Hadaway and F Barlow), 762
Soils (Lateritic) Laterite and (J. A. Prescott and R. L. Pendleton), 871
Soils (New Zealand) Abnormal Thermal Behaviour of α-Quartz from some (M. Fieldes), 366
Soils of a High Organic Matter Content Modification of a Soil Percolation Apparatus for (T. M. B. Payne and P. H. H Gray), 325
Solanum tuberosum, var. *andigenum* · Genotypical Background of Resistance to *Heterodera rostochiensis* in (Dr. H J Toxopeus and C. A. Huijsman), 1016
Solar Corona : Occultation of a Radio Star by the (K. E. Machin and F. G. Smith), 319
Solar Eclipse of February 25, 1952 E Region during the (C. M. Minnis), 453
  Micro-Magnetic Variations during the (Prof. N. F Astbury), 68
Solar Eclipses of September 1, 1951, and February 25, 1952 Radio Observations of the (J.-F. Denisse, E. J Blum and J-L. Steinberg), 191
Solar Outbursts at 8·5-mm Wave-length (John P. Hagen and Nannielou Hepburn), 244
Solid Surfaces . Electron Microscopy of (Electro [illegible] Group of the Institute of Physics Discussion on), 86 [illegible]
Solids : Dielectric Breakdown of (S. Whi [illegible]
  Electrical Breakdown of, *review*, 21 [illegible]
  An Introduction to Luminescence [illegible] *review* by Dr. E. J. Bowen, 259
  Spectrum of the Compton R [illegible] and Gosta Brogren), 886
Solids (Inorganic) Adsorption of Amino-acids on Sparingly Soluble (D J. O'Connor and F. Bryant), 84
Sols (Lyophobic) Stability of (Dr V B. Vouk), 762
Solubility of Melanins (A. J. Lea), 709
Soluble Inorganic Solids Adsorption of Amino-Acids on Sparingly (D. J O'Connor and F. Bryant), 84
Solutes (High Molecular Weight) Use of, in the Study of Isolated Intracellular Structures (Dr. John H. McClendon and Prof. L R Blinks), 577
Solution obtained by Pyridine Extraction of Coal : Nature of the (E. Boult, H. R. Thirsk and H E. Blayden), 317
Solutions (Non-aqueous) Conductance in (R. C. Schonebaum), 422
Solvents (Organic) · Flattening of Meniscus between Water and (Dr. A F. H. Ward and L H Brooks), 118
Soret Effect . The (Dr. C C. Tanner), 34
South African Waters Discovery of *Tetragonurus* Risso, 1810, in (Prof J. L B. Smith), 496
South Australia From Black to White in (Ronald and Catherine Berndt), *review* by D'Arcy Ryan, 551
Southern Hemisphere · The Iris in the, *review* by Dr. H. R. Fletcher, 1037
Southern Marches · The (H. J. Massingham), *review* by T. H. H., 473
Soviet Family Legislation (Dr. R. A. J. Schlesinger), 274
Soviet Union · Science in a Satellite State of the (Society for Freedom in Science, Occasional Pamphlet No. 13), 1049
Space Travel, 486
Spanish Scientific Books (Science Museum Exhibition), 739, 828
Sparing Effect by Formate or Methanol on the Impairment of Creatine Metabolism in Folic Acid Deficiency (Prema Fatterpaker, Urmila Marfatia and Dr. A. Sreenivasan), 894
Spark Discharges Decay of Light to Very Low Levels from (R. H. Johnson and D. E H. Jones), 669
Spawning Reflex in Hypophysectomized Killifish : Induction of a (Grace E. Pickford), 807
Species : Genetics and the Origin of (Prof. Theodosius Dobzhansky), third edition, *review* by Prof. K Mather, 383
Specific Heat of Chromium Oxide (Cr_2O_3) at the Antiferromagnetic Curie Temperature · Anomalous (Dr J. Volger), 1027
Specificity of Vitamin B_{12} for *Euglena* (Dr. William J. Robbins, Annette Hervey and Mary E Stebbins), 845
Spectra Infra-Red, of Coals (R. R. Gordon, W N Adams and G. I. Jenkins), 317
  Molecular, and Molecular Dynamics, *review* by Dr H. W. Thompson, 469
  Molecular, and Molecular Structure (Gerhard Herzberg), 1, Spectra of Diatomic Molecules, second edition, *review* by Dr. H. W. Thompson, 469
Spectra (Infra-Red) . Identification of Organic Compounds from (Dr. A. E. Martin), 20
Spectra of Polyatomic Molecules Electronic Orbitals, Shapes and (Dr A. D. Walsh), 974
Spectrograms taken in Rapid Succession : Great Intensity Variations of H and Effects in Auroral (Prof. L Vegard), 536
Spectrometer Studies on the Decay Schemes of Silver-100, Antimony-124 and Iodine-131 · Scintillation (S. Almqvist and Sven A. E. Johansson), 583
Spectroscope . The Apple and the (T. R. Henn), *review* by H. H. T , 684
Spectrum of the Compton Radiation from Solids (Kessar Alexopoulos and Gosta Brogren), 886
Speed, Error and Difficulty Relationships within a Problem-solving Situation : Some (W. D Furneaux), 37, *erratum*, 269
Sperm Passage of the, and the Penetration of the Egg in Mammals (C. R Austin and A. W. Braden), 919
Sperm (Mammalian) · The 'Capacitation' of (C. R. Austin), 326
  Chemical Composition of (R. Duncan Dallam and Prof. Lloyd E. Thomas), 377
Spiers Memorial Lecture of the Faraday Society (Dr. J. T. Edsall), 518
Spinal Ganglion Neurones of the Toad, *Bufo regularis* Senility Changes in the (Dr. Tohamy A. Moussa), 206
Spinels : A Superstructure in (Dr P. B Braun), 1123
Spiral Growth on Graphite (F. Hubbard Horn), 581
Spiral Nebula NGC 4216 A Diffraction Corona near the Centre of the (Prof Bertil Lindblad and Aina Elvius), *erratum*, 61
Spore Content of the Atmosphere near the Ground (P. H. Gregory), 475
Sporulation Medium for Yeast . Sodium Acetate Agar as a (R. R. Fowell), 578
Spot Test . Quantitative, on Filter Paper and Examples of its Application (Tatsuo Kariyone, Shuichi Shimizu and Dr Yohei Hashimoto), 422
Spray for Amino-Acids Indicator (A. R Kemble and H T Macpherson), 664
Springs (Hot) · Biology of, *review*, 134
Stability of Lyophobic Sols (Dr. V. B. Vouk), 762
Stabilization of Oxidative Phosphorylation in Heart-Muscle Sarcosomes (Dr E. C. Slater and Dr. K. W Cleland), 118
Staining of Striated Muscle with Tetrazolium Compounds . Supra-vital (G Calcutt), 42
Standards of Light at the National Physical Laboratory 405
Standing Light Waves · Adventures with (Prof. H. E. Ives), 1111
Staphylococcus aureus Bacteriophages, Group G · A New Serological Division of (Joan E. Rippon), 287
Starch (Natural and Synthetic). Enzymes for Building (Dr. G. A. Gilbert), 691
Stars : From Atoms to (Dr. Martin Davidson), third edition, *review* by F. M Holborn, 596
  Scintillation of, and the Atmosphere, 305
Stars (Faint) The Astrometry of (International Astronomical Union Symposium on), 786
Stars and Galactic Structure . Variable (Cecilia Payne-Gaposchkin), 223
Starvation (Human) The Biology of (Ancel Keys, Josef Brozek, Austin Henschel, Olaf Mickelsen, Henry Longstreet Taylor), *review* by Dr. E. M. Widdowson, 177
State (Modern) . Academic Freedom in the, 721
State (Welfare) : Industrial Management in the, 811
State Expenditure on Universities in Great Britain, 171
Static and Dynamic Conditions Work-hardening of Annealed Mild Steel under (A. W. Crook), 1124
Statistical Methods for Chemists (W. J. Youden), *review* by Dr. D. J. Finney, 219

Statistical Theory of Atomic Nuclei (Prof. P. Gombás), 362
Statistics : Fellowships in (University of Chicago), 653
Statistics (Quantal) : Introduction to, review by Prof. G. S. Rushbrooke, 682
Statistics for Colonial Agriculture (G. E. Hodnett), 26
Statistics and the Chemist, review by Dr. D. J. Finney, 219
Statistiques quantiques (Georges Guinier), review by Prof. G. S. Rushbrooke, 682
Stauromedusan *Craterolophus tethys* Clark in British Waters (Dr. F. Segrove), 1023
Steel (Alloy) : Delayed Brittle Fracture of, at Low Stress Levels (C. L. M. Cottrell), 1079
Steel (Annealed Mild) : Work-hardening of, under Static and Dynamic Conditions (A. W. Crook), 1124
Stellar Evolution (International Astronomical Union Symposium on), 786
Stereochemistry of the Tropane Alkaloids (Prof. G. Fodor), 278
Stereoptics (Leslie P. Dudley), review by S. Weintroub, 473
Steric Effect of the tert.-Butyl Group (Dr. Malcolm Crawford and F. H. C. Stewart), 322
Sterile Culture of Plant Embryos *in vitro* : A New Technique for the (Pearl Stokes), 242
Sterile Plants : Male, by Chemical Treatment (Dr. S. Rehm), 38
Sterling (Louis) Premium of the British Institution of Radio Engineers awarded to Emlyn Jones, 308
Steroid Hormones : A Symposium on (edited by Edgar S. Gordon), review, 858
Steroid Hormones and Tumors (Dr. Alexander Lipschutz), review by Dr. A. S. Parkes, 178
Steroids (Symposium on, at the Second International Congress of Biochemistry), 444
Stevenson Lecture (Dr. James B. Conant), 215
Stimulating Effect of Amino-Acids on the Survival at 37° C. of *Trypanosoma rhodesiense* in a Serum-free Synthetic Medium (Dr. J. Williamson and L. M. Rollo), 376
Stone Age in Eastern Palestine, review by M. C. Burkitt, 386
Stone Axes : Petrological Identification of, 828
Strains : Internal, and the Bauschinger Effect in Metals ; Magnetic Properties, (D. V. Wilson), 30
Strategy of Science (Sir Henry Tizard), 427
Streaming Potential and Electro-osmosis—A Model for the Mechanism of Streaming Potential (Dr. Horace E. Rose and G. Moss), 836 ; Mechanism of Electro-osmosis (K. L. Nash and N. W. Lister), 837
Streptococcal Bacteriophage Lysis : Enhancement of, by Hyaluronidase (W. R. Maxted), 1020
Stress Levels (Low) : Delayed Brittle Fracture of Alloy Steel at (C. L. M. Cottrell), 1079
Stresses (Boundary) : Photo-Elastic Determination of (William Shelson), 82
Strontium Oxide (SrO) : Ultra-Violet Band System of (Gunnar Almkvist and Dr. Albin Lagerqvist), 885
[illegible]ructural Features of Antitumorigenic Corticoids (Dr. Elvira Mardones, Dr. R. Iglesias, Dr. F. Poenzalida, Dr. S. Bruzzone and Prof. A. Lipschutz), 917
Structure (Molecular) : Molecular Spectra and (Gerhard Herzberg), 1, Spectra of Diatomic Molecules, second edition, review by Dr. H. W. Thompson, 469
Structure of Chloroplasts in Two Flagellates : Fine (J. J. Wolken and G. E. Palade), 114
Structure of Elastic Tissue (Dr. D. A. Hall, Dr. R. Reed and Prof. R. E. Tunbridge), 264
Structure of Lanostenol (R. G. Curtis, J. Fridrichsons and A. McL. Mathieson), 321
Structure of Proteins (Royal Society Discussion on), 53
Structure of Psilomelane, $(Ba,H_2O)_2Mn_5O_{10}$: Role of Water in the (A. D. Wadsley), 973
Structure of White Phosphorus—Single Crystal X-Ray Examination (D. E. C. Corbridge and E. J. Lowe), 629
Structure and Development of the Avian Pituitary from a Comparative and Functional Viewpoint (Karl Georg Wingstrand), review by Dr. A. J. Marshall, 553
Student (Degree) : Botany for the, review by Prof. Frank W. Jane, 257
Students (British) : Fellowships to, for Advanced Study and Travel in the United States (Commonwealth Fund of New York), 524
Studentships in Ecology : Research (Nature Conservancy Awards for 1952), 524
Sub-Fossil Hekla Pumice from Denmark (Prof. A. Noe-Nygaard), 227
Substance in Animal Tissues which stimulates Ketone-Body Excretion (H. B. Stewart and Prof. F. G. Young), 976
Substances naturelles de synthèse (Collection publiée sous la direction de Dr. Léon Velluz), Vol. 3, review by Prof. W. Baker, 817
Substituents : Influence of, on the Mesomorphism of *p*-*n*-Alkoxybenzoic and 6-*n*-Alkoxy-2-Naphthoic Acids (G. W. Gray and Prof. Brynmor Jones), 451
Sugar Components of Blood and Urinary Glycoproteins—Confirmation of the Presence of Fucose by a New Reaction (Deirdre M. Waldron), 461
Sugar Beet Diseases in Ireland (Prof. Robert McKay), review by W. C. Moore, 469
Sugarcane : The, review by Prof. C. W. Wardlaw, 640
  Botany of (Dr. C. van Dillewijn), review by Prof. C. W. Wardlaw, 640
Sugarcane × Bamboo Hybrids (T. S. Raghavan), 329
Sugars : Use of *n*-Butanol–Formic Acid–Water Mixture in the Paper Chromatography of Amino-Acids and (Prof. L. F. Wiggins and J. Howarth Williams), 279
  Paper Electromigration of Flavonoids and, using a High Constant-voltage Current (Dr. Yohei Hashimoto, Itsubiko Mori and Mutsuo Kimura), 975
Sugars (Ketose) : An Extended Orcinol Test Specific for (J. Howarth Williams), 894
Sulphinylureas and Sulphenylureas (Frederick Kurzer), 167
Sulphydryl Groups : Role of, in the Oxidation of Pyruvate (Dr. E. C. Slater), 970
Sun : The Blue, of September 1950 (R. Wilson), 103 ; (E. M. Elsley), 103
  Eclipse of the (Two articles in *L'Astronomie*), 914
Sun's Corona : Tidal Forces in the, due to Planets (K. G. Meldahl), Part 3, 482
Sun's Magnetic Field : Cosmic Rays and the—Apparent Absence of Low-energy Cosmic-ray Primaries (J. A. Van Allen and S. F. Singer), 62 ; Diurnal Variation of Cosmic Rays and the Sun's Magnetic Field (S. F. Singer), 63
Sunspot : A Recent, 143
Sunspot Cycle : Prominence Activity and the (Dr. R. Ananthakrishnan), 156
Sunspots : Planets and, 482
Sunspots during January–April 1952 (Lucy T. Day), 1003
Supernova (Tycho Brahe's) (A.D. 1572) : Radio-Frequency Radiation from (R. Hanbury Brown and C. Hazard), 364
Supersonic Aircraft : The 'Double Bang' of (T. Gold), 808
Superstructure in Spinels (Dr. P. B. Braun), 1123
Supports for Electron Microscopy : Thin Glass Layers as (Prof. A. Van Itterbeek, L. De Greve, G. F. Van Veelen and C. A. F. Tuynman), 795
Suramin (Bayer 205) in Animal Tissues—Demonstration of Bayer 205 (Suramin) in Tissues and its Cellular Distribution ; Visual Demonstration of Immune Reactions in Tissue (Prof. N. Jancsó and Dr. A. Jancsó-Gábor), 567, 568
Surface Activity of Sodium Taurocholate : Hæmolytic and (B. A. Pethica and Dr. J. H. Schulman), 117
Surface Oxide Films in Intermetallic Contacts (M. Cocks), 203
Surgery in the University of Otago, 605
Survival of Adrenal Gland Homografts in the Rabbit's Skin (Dr. D. A. Darcy), 805
Survival of the Perfused Cat's Brain in the Absence of Glucose (A. Geiger, J. Magnes and R. S. Geiger), 754
Survival at 37° C. of *Trypanosoma rhodesiense* in a Serum-free Synthetic Medium : Stimulating Effect of Amino-Acids on the (Dr. J. Williamson and L. M. Rollo), 376
Svenska Linné-Sällskapets Årsskrift, Årg. 33–34, 1950–51, review by Prof. F. J. Cole, 1036
Sweden : Linnean Tradition in, 872
Swiss Flora : Pocket Atlas of the, review by Prof. F. E. Weiss, 431
Sylvester Medal of the Royal Society awarded to Prof. A. S. Besicovitch, 826, 948
Sylviculture of Mixtures in some Forests in S.W. Germany (F. C. Hummel), 652
Symbioses : Parasitism and (Maurice Caullery), translated by Dr. Averil M. Lysaght, review by Dr. G. Lapage, 91
Symbiosis in *Ptilinus pectinicornis* L. (E. A. Parkin), 847
Symmetrical Spherical Top (C. M. Breams), 31 ; (G. N. Copley), 169
Sympathetic Trunks : Rostral Extremities of the (Prof. G. A. G. Mitchell), 533
Synchrotron : The Oxford, 913
Synergistic Interaction between 3-Indolylacetonitrile and 3-Indolylacetic Acid (Daphne J. Osborne), 210
Synthèse : Substances naturelles de (Collection publiée sous la direction de Dr. Léon Velluz), Vol. 3, review by Prof. W. Baker, 817
Synthesis (Peptide-Bond) : Reported Gamma Glutamyl Activation of (Richard W. Hendler and Prof. David M. Greenberg), 123
Synthesis for Aroylacrylic Acids : A Novel (Martin Goldman and Ernest I. Becker), 35
Synthesis of Deoxyribose in Animal Tissues (Mary G. McGeown and Dr. F. H. Malpress), 575
Synthesis of Diphosphopyridine Nucleotide by Cell Nuclei isolated in Aqueous Media (Dr. George H. Hogeboom and Dr. Walter C. Schneider), 374
Synthesis of Flavin-adenine-dinucleotide : Total (S. M. H. Christie, Dr. G. W. Kenner and Prof. A. R. Todd), 924
Synthesis of Glutathione : Enzymic Splitting and (P. J. Fodor, A. Miller and Dr. H. Waelsch), 841
Synthesis of Vitamin B_{12} by *Rhizobium meliloti* (M. O. Burton and A. G. Lockhead), 913
Synthesized by a Soil Bacterium : A Bacterial Growth-Factor (A. G. Lochhead, Margaret O. Burton and R. H. Thexton), 282
Synthetic Action of Almond Emulsin (Prof. Stanley Peat, Dr. W. J. Whelan and Mrs. K. A. Hinson), 1056
Synthetic Medium (Serum-free) : Stimulating Effect of Amino-Acids on the Survival at 37° C. of *Trypanosoma rhodesiense* in a (Dr. J. Williamson and L. M. Rollo), 376
Synthetic Polypeptide : Behaviour of a, analogous to Protein Denaturation (Dr. A. Elliott), 1066

TAINTING of Tobacco by a Dichloropropene-Dichloropropane Soil Fumigant (C. J. Shepherd), 1073
Tanning of Fatty Acid and Protein Monolayers by Metal Ions (Cr, Al, Fe and Cu), (Dr. J. H. Schulman and M. Z. Dogan), 31
Technical Information for Industry : Scientific and, 827
Technical Periodicals published in South-East Asia : Scientific and (Unesco East Asia Science Co-operation Office), 59
Technique of Freezing and Drying Tissues : Edmond About and the (L. G. E. Bell), 547 ; (R. Legendre), 1080
Technological Education in Manchester, 651
Technology (Food) : Problems and Possibilities in, review by A. T. Parsons, 680
Technology (Textile) : Postgraduate Research Scholarships in (Courtauld's Scientific and Educational Trust Fund Awards), 346
Teeth (Rats' Incisor) : Macrophages in the Periodontal Tissues of (Prof. J. T. Irving), 573
Television : The British Contribution to (Institution of Electrical Engineers Convention on), 136
  Broadcasting and, since 1900 (Maurice Gorham), 47
  Broadcasting and, in Great Britain, 45
  Colour (Colour Group of the Physical Society Discussion on), 1094
Television in Wales and Scotland, 481
Television Relay [illegible] to London, 101
Telford Gold [illegible] the Institution of Civil Engineers awarded to Dr. Ca[illegible]0
Telford [illegible]stitution of Civil Engineers awarded to A. A [illegible] R. H. MacDonald and (jointly) to J. T. Calvert
T[illegible] and the Glycogen Content of the Frog's [illegible] C. L. Smith), 74

NDEX

ide · The Living (Prof. N. J. Berrill), *review* by Dr. D. P Wilson, 640
imbers Gold Coast (D. Kinloch and W. A Miller), revised edition, 563
ime and Evolution, *review* by N. W. Pirie, 992
ime and Trace Metals in Archæological Sites (V. P Sokoloff and G. F. Carter), 872
ime Ball Resumption of dropping the (Royal Observatory, Greenwich), 738
ime's Arrow and Evolution (Harold F. Blum), *review* by N. W. Pirie, 992
imes, *The* Survey of British Aviation, 441
issue . Chromatographic Isolation and Estimation of the Natural Œstrogens from (F. L. Mitchell), 621
issue (Animal) Isolation of a Soluble Fibrinolytic Activator from (Dr. Tage Astrup and Agnete Stage), 929
issue (Elastic) Structure of (Dr. D. A. Hall, Dr. R. Reed and Prof R. E. Tunbridge), 264
issue Culture . Growth of Rat Ovary in (Jean I Scott), 208
issue Cultures of Maize Endosperm Effect of, on the Growth of Excised Maize Embryos (Elizabeth A Pieczur), 241
issue Extracts Fibrinolytic Activity of, and of Trypsin (Dr. Tage Astrup and Ida Sterndroff), 981
issue Extracts containing Inorganic Iodide A Possible Source of Artefacts in the Chromatography of (J. D Acland), 32
issues Edmond About and the Technique of Freezing and Drying (L G. E. Ball), 547 , (R Legendre), 1080
issues (Animal) A Substance in, which stimulates Ketone-Body Excretion (H. B. Stewart and Prof. F G. Young), 976
  Suramin (Bayer 205) in—Demonstration of Bayer 205 (Suramin) in Tissues and its Cellular Distribution ; Visual Demonstration of Immune Reactions in Tissue (Prof. N. Jancsó and Dr. A. Jancsó-Gábor), 567, 568
  Synthesis of Deoxyribose in (Mary G. McGeown and Dr. F H. Malpress), 575
ssues (Normal and Neoplastic) Effect of D(+)-Leucine on the Hydrolysis of Glycil-L-Leucine in (Prof. A. Vescia, A. Albano and A Iacono), 804
ssues of Rabbits Distribution of Dextran in the (Bengt H. Persson), 716
tan (Gmelins Handbuch der anorganischen Chemie, achte Auflage, System-Nummer 41), *review*, 902
tanium Origin of the Deformation Textures of (D N. Williams and Prof. D. S. Eppelsheimer), 146
tanium Crystals Growth Spirals originating from Screw Dislocations on Electrolytically produced (M. A. Steinberg), 1119
tmice · Post-fledging Dispersal of Juvenile (Ivan M. Goodbody), 1002
oad, *Bufo regularis* · Senility Changes in the Spinal Ganglion Neurones of the (Dr. Tohamy A. Moussa), 206
obacco · Tainting of, by a Dichloropropene-Dichloropropane Soil Fumigant (C. J Shepherd), 1073
obacco Mosaic Virus Action of Carboxypeptidase on (Dr. J. Ieuan Harris and Dr. C. A. Knight), 613
obacco Mosaic Virus Nucleoprotein Infra-Red Dichroism of (Dr R D. B. Fraser), 491
omatoes (Ripening) · Biosynthesis of Carotenes in (Dr. T. W. Goodwin and Malini Jamikorn), 104
op The Symmetrical Spherical (C. M. Braams), 31 ; (G N. Copley), 169
opographical Studies . Thin-Film Interferometric Techniques for High-Magnification (Prof S Tolansky and M Omar), 81
orsional Vibration of Bars · Effect of Variation in Diameter on the (H. Pursey), 502
otem Poles and Blood Groups (Prof. R Ruggles Gates), 377 ; (G H. S. Bushnell), 377
ouch The World of, *review* by Prof. John Cohen, 815
ownsman's Food (Dr. Magnus Pyke), *review* by Dr. L. H. Lampitt, 552
oxic Principle of *Lathyrus sativus* (Prof. M N. Rudra), 124
oxicity Selective, with Special Reference to Chemotherapy (Prof. Adrien Albert), *review*, 641
oxicity of Contact Insecticides Lipoid Solubility as a Factor in the (Dr S. Pradhan, M. R. G. K. Nair and S. Krishnaswami), 619
oxicity of Dextran in Rats (T. Edlund, B. Lofgren and L. Vali), 125
oxicity of Methylene Blue to *Leptospira icterohaemorrhagiae* (J J. Lawrence), 327
oxicity of Trypan Blue · Effect of Œstradiol Benzoate and Orchidectomy on the (Prof T Nicol and A. A. Zikry), 239
oxicological Actions of Dart Poison used in Malaya . Pharmacological and (Robert Chun Yu Lin), 416
ace-metal Dating of Archæological Sites, 872
acer (Radioactive) : Use of, in the Study of Insect Populations (Lepidoptera), (Dr. H. B. D. Kettlewell), 584
acers (Radioactive) Demonstration by, of the Adsorption of Cations by Metals (Prof. J Palacios and A Baptista), 665
achypogon plumosus (H B. K.) Nees Production of Antibiotic Substances by the Roots of a Grass, and of *Pentanisia variabilis* (E. Mey.) Harv. (Rubiaceæ), (Gordon Stiven), 712
ade Unions (British) The Government of (Dr. Joseph Goldstein), 812
aining in Chemical Engineering Education and (British Association for the Advancement of Science, Section G (Engineering), Discussion on), 644
aining of Designers for the Printing Industry (London and Home Counties Regional Advisory Council), 18
aining for Industry (City and Guilds of London Institute Exhibition), 739
aining of Metallurgists Education and, 989
  Education and (Prof. F C Thompson), 182
ansaminase Cysteic Acid (Sven Darling), 749
ansaminases for Pyridoxamine and Purines (Prof. Carolyn F. Gunsalus and Joseph Tonzetich), 162
ansamination Pyridoxal Derivatives in (Dr J. Baddiley), 711
ansamination Reactions A Simple Paper Chromatographic Method for the Study of (Dr. K. V. Giri, A N. Radhakrishnan and C. S. Vaidyanathan), 1025
ansfer of Heat and Mass : Introduction to the (E. R. G Eckert), *review* by D B Spalding, 1089
ansformation . An Unusual, of Isomeric Forms of Tetraacetyl D-Ribofuranose (Dr. John Davoll, George Bosworth Brown and Donald W. Visser), 64
ansformation of Ovalbumin to Plakalbumin Stepwise Degradation of the Peptides liberated in the (Martin Ottesen and Albert Wollenberger), 801
